Reference Information

Sample Parameter Qualifier key listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
F1-F4-511-CALC-WT	Soil	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-S

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

Hydrocarbon results are expressed on a dry weight basis.

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT	Soil	F1-O.Reg 153/04 (July 2011)	E3398/CCME TIER 1-HS

Fraction F1 is determined by extracting a soil or sediment sample as received with methanol, then analyzing by headspace-GC/FID.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F2-F4-511-WT	Soil	F2-F4-O.Reg 153/04 (July 2011)	CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from soil with 1:1 hexane:acetone using a rotary extractor. Extracts are treated with silica gel to remove polar organic interferences. F2, F3, & F4 are analyzed by GC-FID. F4G-sg is analyzed gravimetrically.

Notes:
1. F2 (C10-C16): Sum of all hydrocarbons that elute between nC10 and nC16.
2. F3 (C16-C34): Sum of all hydrocarbons that elute between nC16 and nC34.
3. F4 (C34-C50): Sum of all hydrocarbons that elute between nC34 and nC50.
4. F4G: Gravimetric Heavy Hydrocarbons
5. F4G-sg: Gravimetric Heavy Hydrocarbons (F4G) after silica gel treatment.
6. Where both F4 (C34-C50) and F4G-sg are reported for a sample, the larger of the two values is used for comparison against the relevant CCME guideline for F4.
7. F4G-sg cannot be added to the C6 to C50 hydrocarbon results to obtain an estimate of total extractable hydrocarbons.
8. This method is validated for use.
9. Data from analysis of validation and quality control samples is available upon request.
10. Reported results are expressed as milligrams per dry kilogram, unless otherwise indicated.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

MET-200.2-CCMS-WT	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020B (mod)

Soil/sediment is dried, disaggregated, and sieved (2 mm). For tests intended to support Ontario regulations, the <2mm fraction is ground to pass through a 0.355 mm sieve. Strong Acid Leachable Metals in the <2mm fraction are solubilized by heated digestion with nitric and hydrochloric acids. Instrumental analysis is by Collision / Reaction Cell ICPMS.

Limitations: This method is intended to liberate environmentally available metals. Silicate minerals are not solubilized. Some metals may be only partially recovered (matrix dependent), including Al, Ba, Be, Cr, S, Sr, Ti, Tl, V, W, and Zr. Elemental Sulfur may be poorly recovered by this method. Volatile forms of sulfur (e.g. sulfide, H2S) may be excluded if lost during sampling, storage, or digestion.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

Reference Information

MOISTURE-WT	Soil	% Moisture	CCME PHC in Soil - Tier 1 (mod)
VOC-1,3-DCP-CALC-WT	Soil	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Soil	VOC-O.Reg 153/04 (July 2011)	SW846 8260 (511)

Soil and sediment samples are extracted in methanol and analyzed by headspace-GC/MS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Soil	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

17-624784

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Sample Parameter Qualifier Definitions:

Qualifier	Description
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

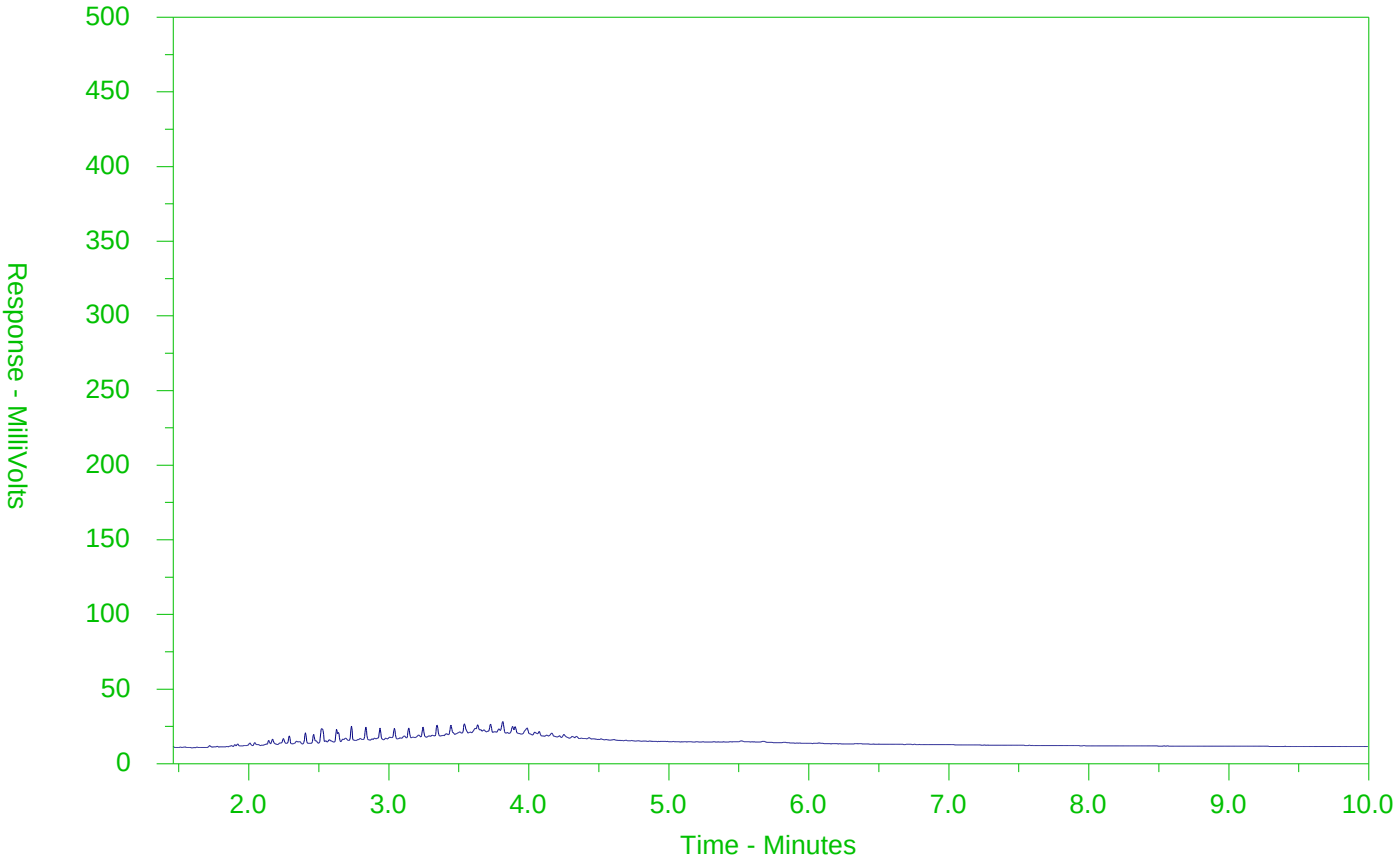
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2134047-2
Client Sample ID: BH18-205-2



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C
346°F	549°F	898°F	1067°F
Gasoline →		← Motor Oils/Lube Oils/Grease →	
← Diesel/Jet Fuels →			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

Sample Parameter Qualifier key listed:

Qualifier	Description
DLS	Detection Limit Adjusted: Instrument Sensitivity

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
B-HWS-R511-WT	Soil	Boron-HWE-O.Reg 153/04 (July 2011)	HW EXTR, EPA 6010B

A dried solid sample is extracted with calcium chloride, the sample undergoes a heating process. After cooling the sample is filtered and analyzed by ICP/OES.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

CN-WAD-R511-WT	Soil	Cyanide (WAD)-O.Reg 153/04 (July 2011)	MOE 3015/APHA 4500CN I-WAD

The sample is extracted with a strong base for 16 hours, and then filtered. The filtrate is then distilled where the cyanide is converted to cyanogen chloride by reacting with chloramine-T, the cyanogen chloride then reacts with a combination of barbituric acid and isonicotinic acid to form a highly colored complex.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

CR-CR6-IC-WT	Soil	Hexavalent Chromium in Soil	SW846 3060A/7199

This analysis is carried out using procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846, Method 7199, published by the United States Environmental Protection Agency (EPA). The procedure involves analysis for chromium (VI) by ion chromatography using diphenylcarbazide in a sulphuric acid solution.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

EC-WT	Soil	Conductivity (EC)	MOEE E3138

A representative subsample is tumbled with de-ionized (DI) water. The ratio of water to soil is 2:1 v/w. After tumbling the sample is then analyzed by a conductivity meter.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

F1-F4-511-CALC-WT	Soil	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-S

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

Hydrocarbon results are expressed on a dry weight basis.

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT	Soil	F1-O.Reg 153/04 (July 2011)	E3398/CCME TIER 1-HS

Fraction F1 is determined by extracting a soil or sediment sample as received with methanol, then analyzing by headspace-GC/FID.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

Reference Information

F2-F4-511-WT	Soil	F2-F4-O.Reg 153/04 (July 2011)	CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from soil with 1:1 hexane:acetone using a rotary extractor. Extracts are treated with silica gel to remove polar organic interferences. F2, F3, & F4 are analyzed by GC-FID. F4G-sg is analyzed gravimetrically.

Notes:
1. F2 (C10-C16): Sum of all hydrocarbons that elute between nC10 and nC16.
2. F3 (C16-C34): Sum of all hydrocarbons that elute between nC16 and nC34.
3. F4 (C34-C50): Sum of all hydrocarbons that elute between nC34 and nC50.
4. F4G: Gravimetric Heavy Hydrocarbons
5. F4G-sg: Gravimetric Heavy Hydrocarbons (F4G) after silica gel treatment.
6. Where both F4 (C34-C50) and F4G-sg are reported for a sample, the larger of the two values is used for comparison against the relevant CCME guideline for F4.
7. F4G-sg cannot be added to the C6 to C50 hydrocarbon results to obtain an estimate of total extractable hydrocarbons.
8. This method is validated for use.
9. Data from analysis of validation and quality control samples is available upon request.
10. Reported results are expressed as milligrams per dry kilogram, unless otherwise indicated.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F4G-ADD-511-WT	Soil	F4G SG-O.Reg 153/04 (July 2011)	MOE DECPH-E3398/CCME TIER 1

F4G, gravimetric analysis, is determined if the chromatogram does not return to baseline at or before C50. A soil sample is extracted with a solvent mix, the solvent is evaporated and the weight of the residue is determined.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

HG-200.2-CVAA-WT	Soil	Mercury in Soil by CVAAS	EPA 200.2/1631E (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAAS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

MET-200.2-CCMS-WT	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020B (mod)

Soil/sediment is dried, disaggregated, and sieved (2 mm). For tests intended to support Ontario regulations, the <2mm fraction is ground to pass through a 0.355 mm sieve. Strong Acid Leachable Metals in the <2mm fraction are solubilized by heated digestion with nitric and hydrochloric acids. Instrumental analysis is by Collision / Reaction Cell ICPMS.

Limitations: This method is intended to liberate environmentally available metals. Silicate minerals are not solubilized. Some metals may be only partially recovered (matrix dependent), including Al, Ba, Be, Cr, S, Sr, Ti, Tl, V, W, and Zr. Elemental Sulfur may be poorly recovered by this method. Volatile forms of sulfur (e.g. sulfide, H2S) may be excluded if lost during sampling, storage, or digestion.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

METHYLNAPS-CALC-WT	Soil	ABN-Calculated Parameters	SW846 8270
MOISTURE-WT	Soil	% Moisture	CCME PHC in Soil - Tier 1 (mod)
PAH-511-WT	Soil	PAH-O.Reg 153/04 (July 2011)	SW846 3510/8270

A representative sub-sample of soil is fortified with deuterium-labelled surrogates and a mechanical shaking techniqueis used to extract the sample with a mixture of methanol and toluene. The extracts are concentrated and analyzed by GC/MS. Results for benzo(b) fluoranthene may include contributions from benzo(j)fluoranthene, if also present in the sample.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

PH-WT	Soil	pH	MOEE E3137A

A minimum 10g portion of the sample is extracted with 20mL of 0.01M calcium chloride solution by shaking for at least 30 minutes. The aqueous layer is separated from the soil and then analyzed using a pH meter and electrode.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

Reference Information

SAR-R511-WT	Soil	SAR-O.Reg 153/04 (July 2011)	SW846 6010C

A dried, disaggregated solid sample is extracted with deionized water, the aqueous extract is separated from the solid, acidified and then analyzed using a ICP/OES. The concentrations of Na, Ca and Mg are reported as per CALA requirements for calculated parameters. These individual parameters are not for comparison to any guideline.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

VOC-1,3-DCP-CALC-WT	Soil	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Soil	VOC-O.Reg 153/04 (July 2011)	SW846 8260 (511)

Soil and sediment samples are extracted in methanol and analyzed by headspace-GC/MS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Soil	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

17-615353

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
E	Matrix Spike recovery outside ALS DQO due to heterogeneous analyte background in sample.
J	Duplicate results and limits are expressed in terms of absolute difference.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

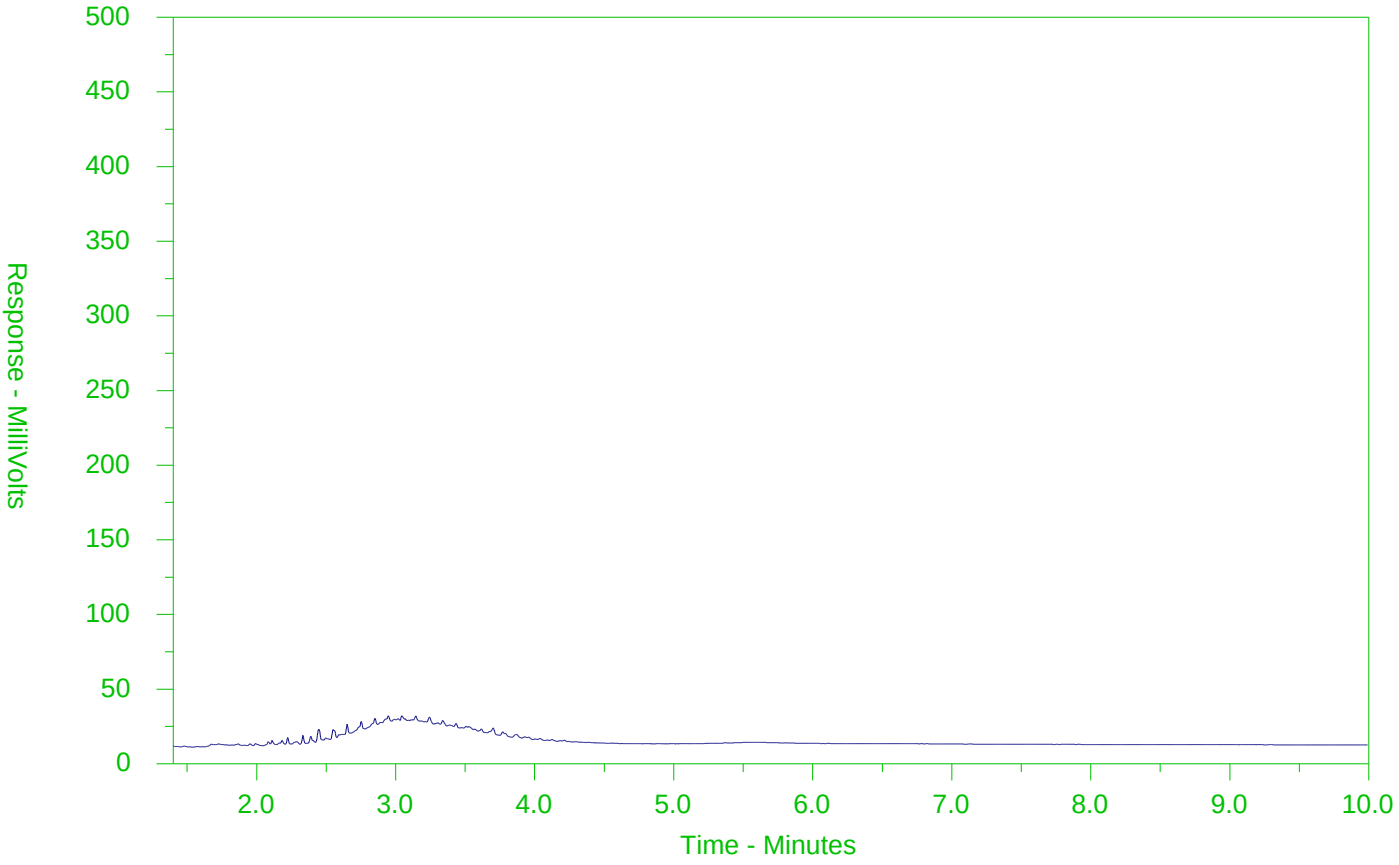
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2136825-8
Client Sample ID: MW18-129D-3



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C
346°F	549°F	898°F	1067°F
Gasoline →		← Motor Oils/Lube Oils/Grease →	
←Diesel/Jet Fuels→			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

Reference Information

Sample Parameter Qualifier key listed:

Qualifier	Description
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
BTX-511-HS-WT	Soil	BTEX-O.Reg 153/04 (July 2011)	SW846 8260

BTX is determined by extracting a soil or sediment sample as received with methanol, then analyzing by headspace-GC/MS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

F1-F4-511-CALC-WT	Soil	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-S

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

Hydrocarbon results are expressed on a dry weight basis.

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT	Soil	F1-O.Reg 153/04 (July 2011)	E3398/CCME TIER 1-HS

Fraction F1 is determined by extracting a soil or sediment sample as received with methanol, then analyzing by headspace-GC/FID.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F2-F4-511-WT	Soil	F2-F4-O.Reg 153/04 (July 2011)	CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from soil with 1:1 hexane:acetone using a rotary extractor. Extracts are treated with silica gel to remove polar organic interferences. F2, F3, & F4 are analyzed by GC-FID. F4G-sg is analyzed gravimetrically.

Notes:
1. F2 (C10-C16): Sum of all hydrocarbons that elute between nC10 and nC16.
2. F3 (C16-C34): Sum of all hydrocarbons that elute between nC16 and nC34.
3. F4 (C34-C50): Sum of all hydrocarbons that elute between nC34 and nC50.
4. F4G: Gravimetric Heavy Hydrocarbons
5. F4G-sg: Gravimetric Heavy Hydrocarbons (F4G) after silica gel treatment.
6. Where both F4 (C34-C50) and F4G-sg are reported for a sample, the larger of the two values is used for comparison against the relevant CCME guideline for F4.
7. F4G-sg cannot be added to the C6 to C50 hydrocarbon results to obtain an estimate of total extractable hydrocarbons.
8. This method is validated for use.
9. Data from analysis of validation and quality control samples is available upon request.
10. Reported results are expressed as milligrams per dry kilogram, unless otherwise indicated.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F4G-ADD-511-WT	Soil	F4G SG-O.Reg 153/04 (July 2011)	MOE DECPH-E3398/CCME TIER 1

F4G, gravimetric analysis, is determined if the chromatogram does not return to baseline at or before C50. A soil sample is extracted with a solvent mix, the solvent is evaporated and the weight of the residue is determined.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

Reference Information

MET-200.2-CCMS-WT	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020B (mod)

Soil/sediment is dried, disaggregated, and sieved (2 mm). For tests intended to support Ontario regulations, the <2mm fraction is ground to pass through a 0.355 mm sieve. Strong Acid Leachable Metals in the <2mm fraction are solubilized by heated digestion with nitric and hydrochloric acids. Instrumental analysis is by Collision / Reaction Cell ICPMS.

Limitations: This method is intended to liberate environmentally available metals. Silicate minerals are not solubilized. Some metals may be only partially recovered (matrix dependent), including Al, Ba, Be, Cr, S, Sr, Ti, Tl, V, W, and Zr. Elemental Sulfur may be poorly recovered by this method. Volatile forms of sulfur (e.g. sulfide, H2S) may be excluded if lost during sampling, storage, or digestion.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

METHYLNAPS-CALC-WT	Soil	ABN-Calculated Parameters	SW846 8270
MOISTURE-WT	Soil	% Moisture	CCME PHC in Soil - Tier 1 (mod)
PAH-511-WT	Soil	PAH-O.Reg 153/04 (July 2011)	SW846 3510/8270

A representative sub-sample of soil is fortified with deuterium-labelled surrogates and a mechanical shaking techniqueis used to extract the sample with a mixture of methanol and toluene. The extracts are concentrated and analyzed by GC/MS. Results for benzo(b) fluoranthene may include contributions from benzo(j)fluoranthene, if also present in the sample.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Soil	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

17-615352

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
DUP-H,J	Duplicate results outside ALS DQO, due to sample heterogeneity. Duplicate results and limits are expressed in terms of absolute difference.
E	Matrix Spike recovery outside ALS DQO due to heterogeneous analyte background in sample.
J	Duplicate results and limits are expressed in terms of absolute difference.
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

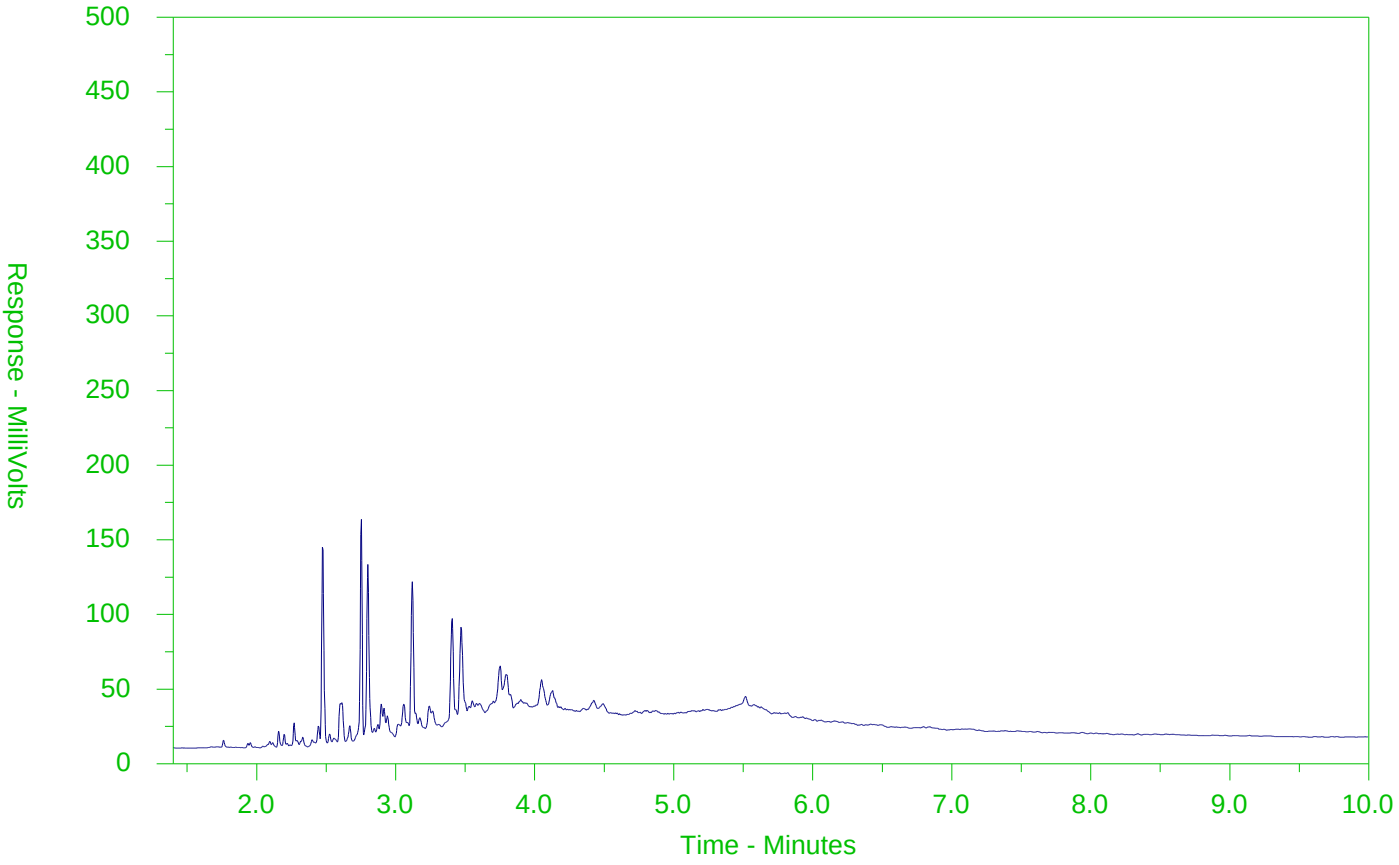
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2136911-5
Client Sample ID: MW18-117S-1



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C
346°F	549°F	898°F	1067°F
Gasoline →		← Motor Oils/Lube Oils/Grease →	
←Diesel/Jet Fuels→			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

T6-Ground Water-All Types of Property Uses

#1: T6-Ground Water-All Types of Property Uses

Reference Information

Sample Parameter Qualifier key listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
F1-F4-511-CALC-WT	Water	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-L

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT	Water	F1-O.Reg 153/04 (July 2011)	E3398/CCME TIER 1-HS

Fraction F1 is determined by analyzing by headspace-GC/FID.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F2-F4-511-WT	Water	F2-F4-O.Reg 153/04 (July 2011)	EPA 3511/CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from water using a hexane micro-extraction technique. Instrumental analysis is by GC-FID, as per the Reference Method for the Canada-Wide Standard for Petroleum Hydrocarbons in Soil Tier 1 Method, CCME, 2001.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

MET-D-UG/L-MS-WT	Water	Diss. Metals in Water by ICPMS (ug/L)	EPA 200.8

The metal constituents of a non-acidified sample that pass through a membrane filter prior to ICP/MS analysis.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

METHYLNAPS-CALC-WT	Water	PAH-Calculated Parameters	SW846 8270
PAH-511-WT	Water	PAH-O. Reg 153/04 (July 2011)	SW846 3510/8270

Aqueous samples, fortified with surrogates, are extracted using liquid/liquid extraction technique. The sample extracts are concentrated and then analyzed using GC/MS. Results for benzo(b) fluoranthene may include contributions from benzo(j)fluoranthene, if also present in the sample.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260

Liquid samples are analyzed by headspace GC/MSD.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

Reference Information

XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Quality Control Report

Workorder: L2139225 Report Date: 08-AUG-18

Client: CH2M HILL CANADA LIMITED
72 VICTORIA ST S, SUITE 300
KITCHENER ON N2G 4Y9
Contact: TANIA MCCARTHY

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
MES	Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

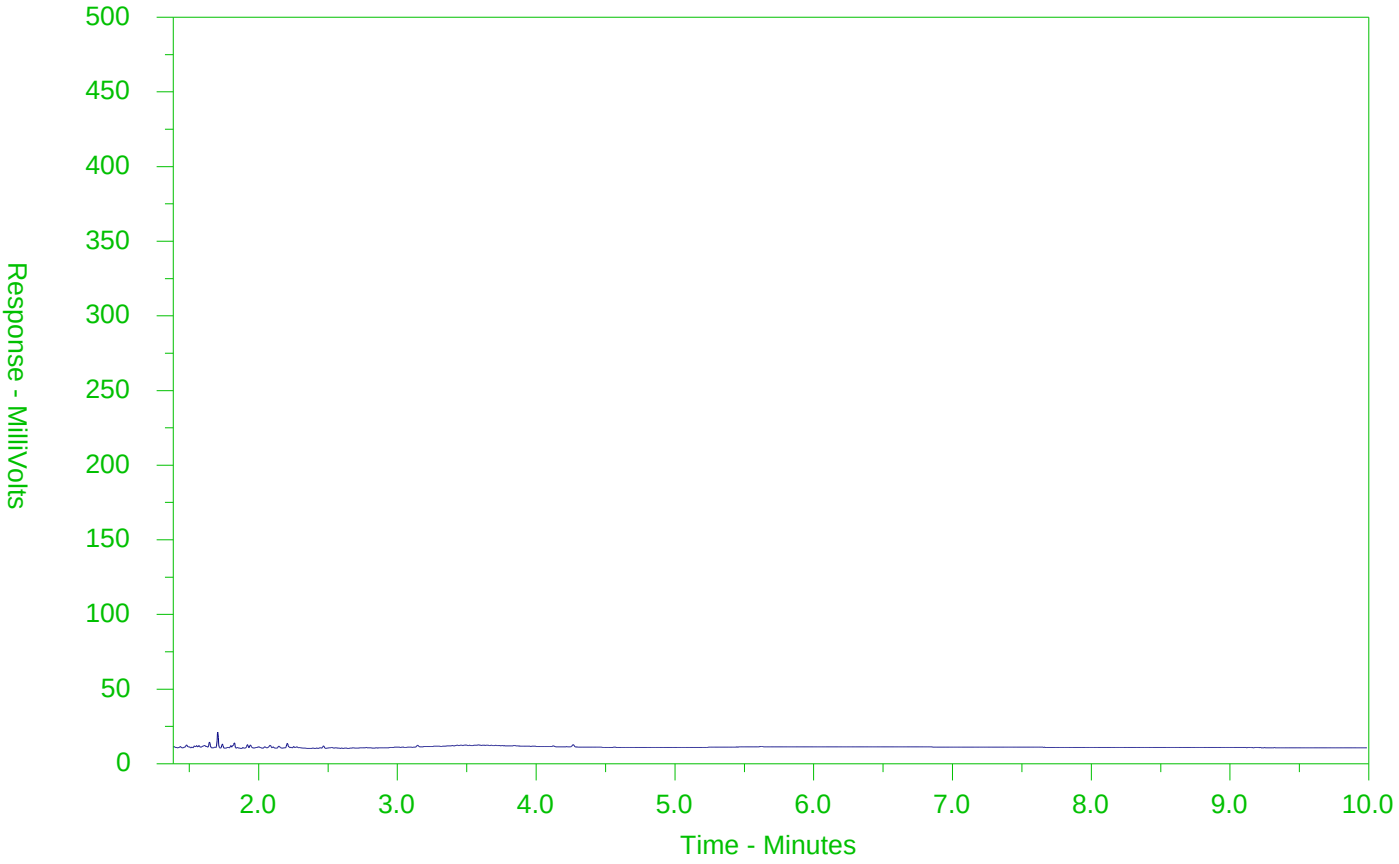
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2139225-5
Client Sample ID: MW18-128D



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C
346°F	549°F	898°F	1067°F
Gasoline →		← Motor Oils/Lube Oils/Grease →	
← Diesel/Jet Fuels →			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

Report Date: 14-APR-21 14:53 (MT)
Version: FINAL REV. 2

Client Phone: 519-579-3500

Certificate of Analysis

Lab Work Order #: L2140486

Project P.O. #: NOT SUBMITTED
Job Reference: 694757
C of C Numbers: 17-626955
Legal Site Desc:

Comments: 13-APR-21:
L2140486-1, 2, 4, 6 - results for Bismuth, Iron, Calcium and Magnesium included.

Mathy Mahadeva
Account Manager

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
B-HWS-R511-WT	Soil	Boron-HWE-O.Reg 153/04 (July 2011)	HW EXTR, EPA 6010B

A dried solid sample is extracted with calcium chloride, the sample undergoes a heating process. After cooling the sample is filtered and analyzed by ICP/OES.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

CN-WAD-R511-WT	Soil	Cyanide (WAD)-O.Reg 153/04 (July 2011)	MOE 3015/APHA 4500CN I-WAD

The sample is extracted with a strong base for 16 hours, and then filtered. The filtrate is then distilled where the cyanide is converted to cyanogen chloride by reacting with chloramine-T, the cyanogen chloride then reacts with a combination of barbituric acid and isonicotinic acid to form a highly colored complex.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

CR-CR6-IC-WT	Soil	Hexavalent Chromium in Soil	SW846 3060A/7199

This analysis is carried out using procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846, Method 7199, published by the United States Environmental Protection Agency (EPA). The procedure involves analysis for chromium (VI) by ion chromatography using diphenylcarbazide in a sulphuric acid solution.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

EC-WT	Soil	Conductivity (EC)	MOEE E3138

A representative subsample is tumbled with de-ionized (DI) water. The ratio of water to soil is 2:1 v/w. After tumbling the sample is then analyzed by a conductivity meter.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

F1-F4-511-CALC-WT	Soil	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-S

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

Hydrocarbon results are expressed on a dry weight basis.

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT	Soil	F1-O.Reg 153/04 (July 2011)	E3398/CCME TIER 1-HS

Fraction F1 is determined by extracting a soil or sediment sample as received with methanol, then analyzing by headspace-GC/FID.

Reference Information

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F2-F4-511-WT Soil F2-F4-O.Reg 153/04 (July 2011) CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from soil with 1:1 hexane:acetone using a rotary extractor. Extracts are treated with silica gel to remove polar organic interferences. F2, F3, & F4 are analyzed by GC-FID. F4G-sg is analyzed gravimetrically.

Notes:
1. F2 (C10-C16): Sum of all hydrocarbons that elute between nC10 and nC16.
2. F3 (C16-C34): Sum of all hydrocarbons that elute between nC16 and nC34.
3. F4 (C34-C50): Sum of all hydrocarbons that elute between nC34 and nC50.
4. F4G: Gravimetric Heavy Hydrocarbons
5. F4G-sg: Gravimetric Heavy Hydrocarbons (F4G) after silica gel treatment.
6. Where both F4 (C34-C50) and F4G-sg are reported for a sample, the larger of the two values is used for comparison against the relevant CCME guideline for F4.
7. F4G-sg cannot be added to the C6 to C50 hydrocarbon results to obtain an estimate of total extractable hydrocarbons.
8. This method is validated for use.
9. Data from analysis of validation and quality control samples is available upon request.
10. Reported results are expressed as milligrams per dry kilogram, unless otherwise indicated.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

HG-200.2-CVAA-WT Soil Mercury in Soil by CVAAS EPA 200.2/1631E (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAAS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

MET-200.2-CCMS-WT Soil Metals in Soil by CRC ICPMS EPA 200.2/6020B (mod)

Soil/sediment is dried, disaggregated, and sieved (2 mm). For tests intended to support Ontario regulations, the <2mm fraction is ground to pass through a 0.355 mm sieve. Strong Acid Leachable Metals in the <2mm fraction are solubilized by heated digestion with nitric and hydrochloric acids. Instrumental analysis is by Collision / Reaction Cell ICPMS.

Limitations: This method is intended to liberate environmentally available metals. Silicate minerals are not solubilized. Some metals may be only partially recovered (matrix dependent), including Al, Ba, Be, Cr, S, Sr, Ti, Tl, V, W, and Zr. Elemental Sulfur may be poorly recovered by this method. Volatile forms of sulfur (e.g. sulfide, H2S) may be excluded if lost during sampling, storage, or digestion.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

METHYLNAPS-CALC-WT Soil ABN-Calculated Parameters SW846 8270

MOISTURE-WT Soil % Moisture CCME PHC in Soil - Tier 1 (mod)

PAH-511-WT Soil PAH-O.Reg 153/04 (July 2011) SW846 3510/8270

A representative sub-sample of soil is fortified with deuterium-labelled surrogates and a mechanical shaking techniqueis used to extract the sample with a mixture of methanol and toluene. The extracts are concentrated and analyzed by GC/MS. Results for benzo(b) fluoranthene may include contributions from benzo(j)fluoranthene, if also present in the sample.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

PCB-511-WT Soil PCB-O.Reg 153/04 (July 2011) SW846 3510/8082

An aliquot of a solid sample is extracted with a solvent, extract is cleaned up and analyzed on the GC/MS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

PH-WT Soil pH MOEE E3137A

A minimum 10g portion of the sample is extracted with 20mL of 0.01M calcium chloride solution by shaking for at least 30 minutes. The aqueous layer is separated from the soil and then analyzed using a pH meter and electrode.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

Reference Information

SAR-R511-WT	Soil	SAR-O.Reg 153/04 (July 2011)	SW846 6010C

A dried, disaggregated solid sample is extracted with deionized water, the aqueous extract is separated from the solid, acidified and then analyzed using a ICP/OES. The concentrations of Na, Ca and Mg are reported as per CALA requirements for calculated parameters. These individual parameters are not for comparison to any guideline.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

VOC-1,3-DCP-CALC-WT	Soil	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Soil	VOC-O.Reg 153/04 (July 2011)	SW846 8260 (511)

Soil and sediment samples are extracted in methanol and analyzed by headspace-GC/MS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Soil	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

17-626955

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

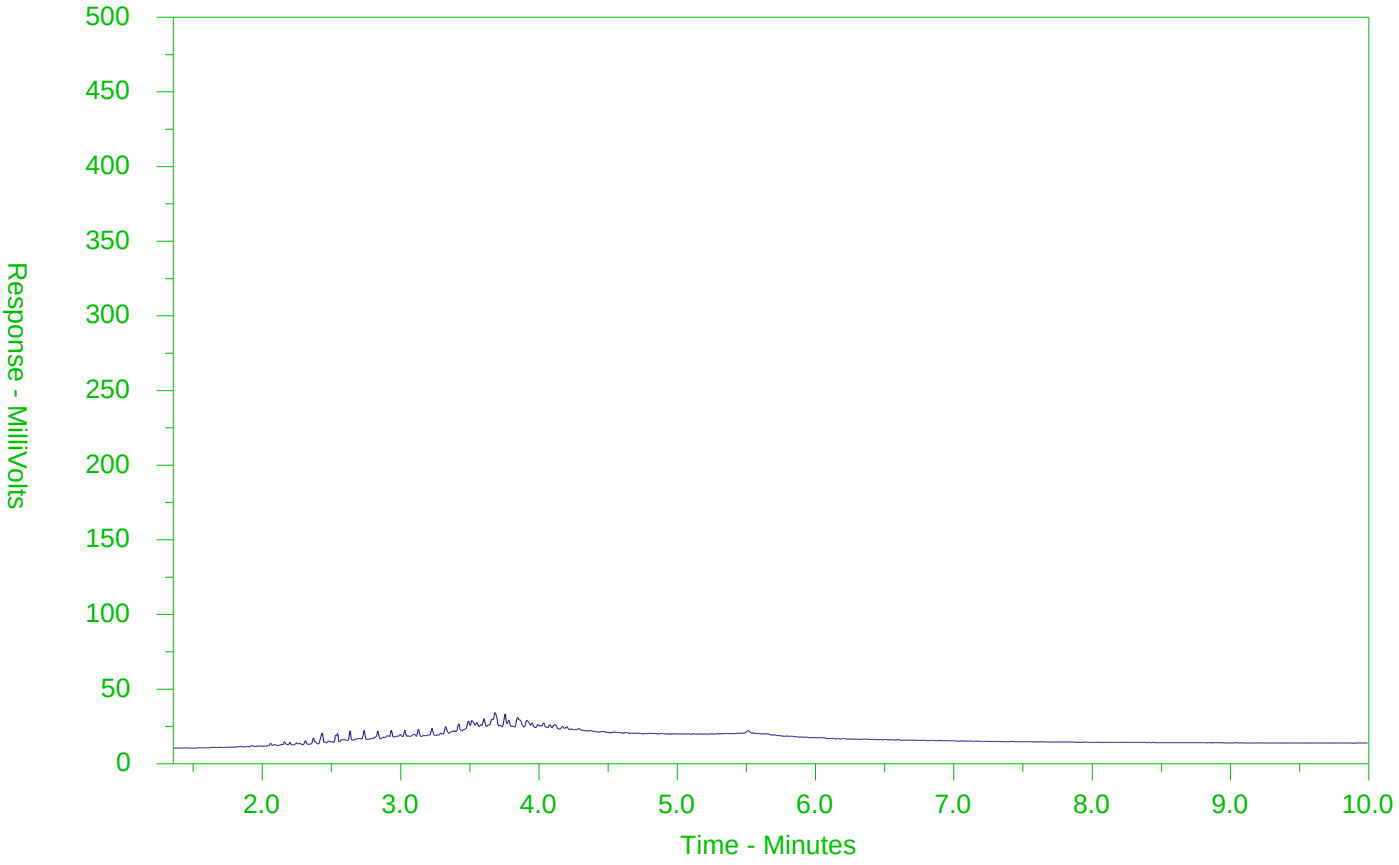
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2140486-4
Client Sample ID: MW18-125S-2



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C
346°F	549°F	898°F	1067°F
Gasoline →		← Motor Oils/Lube Oils/Grease →	
←Diesel/Jet Fuels→			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

Reference Information

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
CN-TCLP-WT	Waste	Cyanide for O. Reg 347	APHA 4500CN C E
ETL-TVH,TEH-TCLP-WT	Waste	CCME Total Hydrocarbons	CCME CWS-PHC, Pub #1310, Dec 2001
F-TCLP-WT	Waste	Fluoride (F) for O. Reg 347	APHA 4110 B-Ion Chromatography
F1-TCLP-WT	Waste	O. Reg 347 TCLP leachable F1	SW846 8260
F2-F4-TCLP-WT	Waste	O. Reg 347 TCLP leachable F2-F4	MOE DECPH-E3398/CCME TIER 1
HG-TCLP-WT	Waste	Mercury (CVAA) for O.Reg 347	SW846 7470A
IGNITABILITY-WT	Waste	O. Reg 347 Ignitability	EPA SW846, Method 1030, 1996

Preliminary Screening Test:
Prepare a sample "as received" 250 mm long by 20 mm wide by 10 mm high. Apply the tip of the flame to the end of the sample strip.
If the sample is non-metallic, hold the flame tip on the sample until the sample ignites or for a maximum of 2 minutes. If combustion occurs, begin timing with a stop watch and note whether the sample propagates up to the 200 mm mark within the 2 minute test period.
If the sample is metal or metal alloy powder, hold the flame tip on the sample until the sample ignites or for a maximum of 5 minutes. If combusiton occurs, begin timing with a stop watch and note whether the sample propagates up to the 200 mm mark within the 20 minute test period.
Note: If the waste propagates burning of 200 mm of the test strip within 2 minutes (20 minutes for metals), the material must be evaluated by the burning rate test.
Burning Rate Test:
Refer to section 7.2 of EPA Method 1030. Samples that have a burning rate of greater than 2.2 mm/s are considered to have a positive result for ignitability according to DOT regulations. For metallic samples , the burning rate must be greater than 0.17 mm/s.

LEACH-TCLP-WT	Waste	Leachate Procedure for Reg 347	EPA 1311

Inorganic and Semi-Volatile Organic contaminants are leached from waste samples in strict accordance with US EPA Method 1311, "Toxicity Characteristic Leaching Procedure" (TCLP). Test results are reported in leachate concentration units (normally mg/L).

MET-TCLP-WT	Waste	O.Reg 347 TCLP Leachable Metals	EPA 200.8
N2N3-TCLP-WT	Waste	Nitrate/Nitrite-N for O. Reg 347	APHA 4110 B-Ion Chromatography
PAH-TCLP-WT	Waste	PAH for O. Reg 347	SW846 8270 (PAH)

Samples are leached according to TCLP protocol and then the aqueous leachate is extracted and the resulting extracts are analyzed on GC/MSD. Depending on the analytical GC/MS column used benzo(j)fluoranthene may chromatographically co-elute with benzo(b)fluoranthene or benzo(k)fluoranthene.

PCB-TCLP-WT	Waste	PCBs for O. Reg 347	SW846 8270
VOC-TCLP-WT	Waste	VOC for O. Reg 347	SW846 8260

A sample of waste is leached in a zero headspace extractor at 30–2 rpm for 18–2.0 hours with the appropriate leaching solution. After tumbling the leachate is analyzed directly by headspace technology, followed by GC/MS using internal standard quantitation.

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

Reference Information

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Application of guidelines is provided "as is" without warranty of any kind, either expressed or implied, including, but not limited to, fitness for a particular purpose, or non-infringement. ALS assumes no responsibility for errors or omissions in the information. Guideline limits are not adjusted for the hardness, pH or temperature of the sample (the most conservative values are used). Measurement uncertainty is not applied to test results prior to comparison with specified criteria values.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
LCS-L	Lab Control Sample recovery was below ALS DQO. Reference Material and/or Matrix Spike results were acceptable. Non-detected sample results are considered reliable. Other results, if reported, have been qualified.
MES	Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

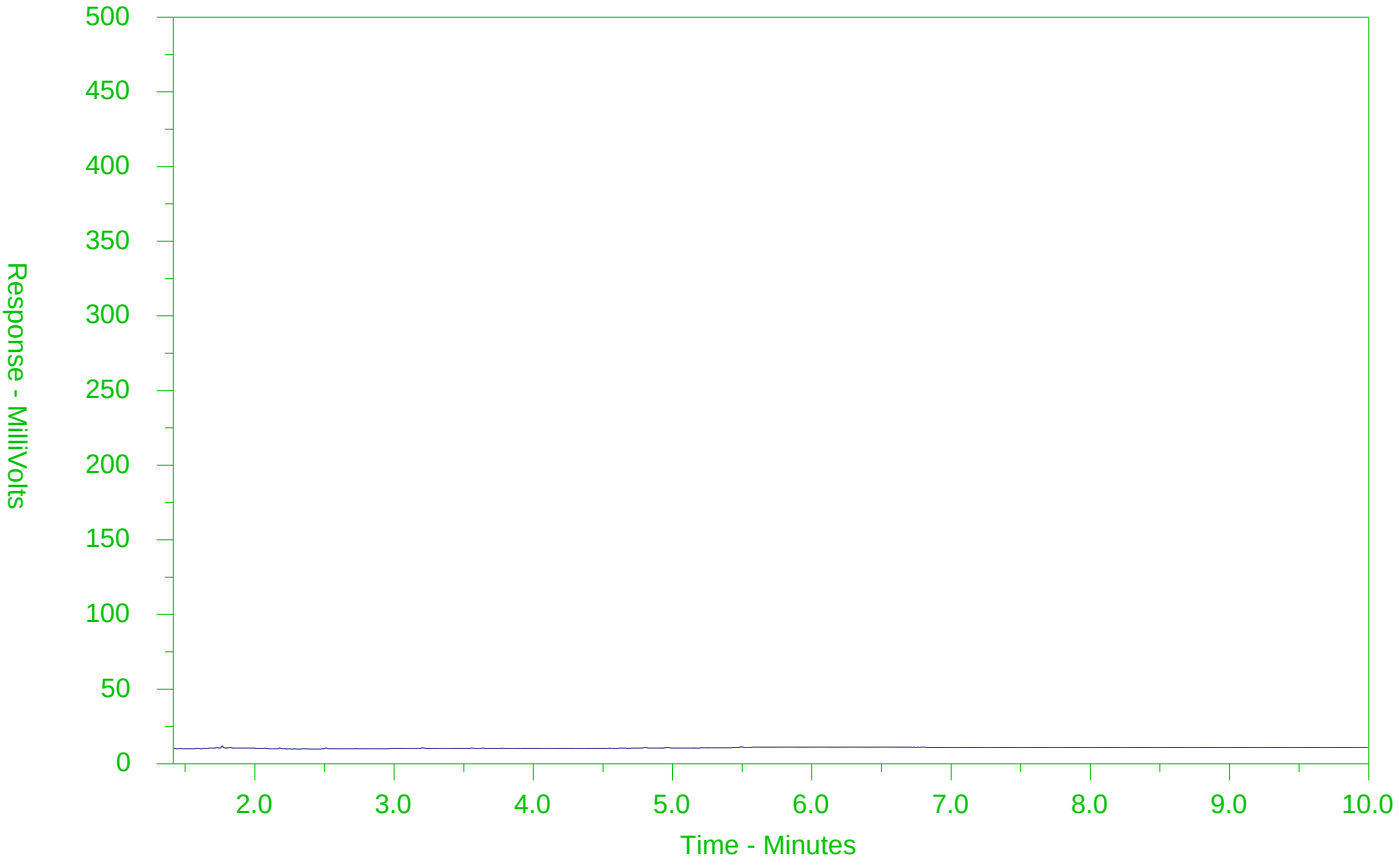
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2140617-1
Client Sample ID: TCLP



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C
346°F	549°F	898°F	1067°F
Gasoline →		← Motor Oils/Lube Oils/Grease →	
←Diesel/Jet Fuels→			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Laboratory Control Sample	Dichlorodifluoromethane	LCS-H	L2141576-10, -11, -12, -5, -8, -9
Laboratory Control Sample	n-Hexane	MES	L2141576-16
Matrix Spike	Barium (Ba)-Dissolved	MS-B	L2141576-1, -10, -13, -15, -16, -17, -19, -2, -3, -4, -5, -6
Matrix Spike	Boron (B)-Dissolved	MS-B	L2141576-1, -10, -13, -15, -16, -17, -19, -2, -3, -4, -5, -6
Matrix Spike	Molybdenum (Mo)-Dissolved	MS-B	L2141576-1, -10, -13, -15, -16, -17, -19, -2, -3, -4, -5, -6
Matrix Spike	Sodium (Na)-Dissolved	MS-B	L2141576-1, -10, -13, -15, -16, -17, -19, -2, -3, -4, -5, -6

Sample Parameter Qualifier key listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).
DLQ	Detection Limit raised due to co-eluting interference. GCMS qualifier ion ratio did not meet acceptance criteria.
DLS	Detection Limit Adjusted: Instrument Sensitivity
LCS-H	Lab Control Sample recovery was above ALS DQO. Non-detected sample results are considered reliable. Other results, if reported, have been qualified.
MES	Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
PRAR	PCB Pattern Most Closely Resembles Aroclor Reported
R	The ion abundance ratio(s) did not meet the acceptance criteria. Value is an estimated maximum.
VTHS	Volatile test was conducted on sample with headspace. Results may be biased low.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
F1-F4-511-CALC-WT	Water	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-L

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT	Water	F1-O.Reg 153/04 (July 2011)	E3398/CCME TIER 1-HS

Fraction F1 is determined by analyzing by headspace-GC/FID.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F2-F4-511-WT	Water	F2-F4-O.Reg 153/04 (July 2011)	EPA 3511/CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from water using a hexane micro-extraction technique. Instrumental analysis is by GC-FID, as per the Reference Method for the Canada-Wide Standard for Petroleum Hydrocarbons in Soil Tier 1 Method, CCME, 2001.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

MET-D-UG/L-MS-WT	Water	Diss. Metals in Water by ICPMS (ug/L)	EPA 200.8

The metal constituents of a non-acidified sample that pass through a membrane filter prior to ICP/MS analysis.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG

Reference Information

must be reported).

METHYLNAPS-CALC-WT	Water	PAH-Calculated Parameters	SW846 8270

PAH-511-WT Water PAH-O. Reg 153/04 (July 2011) SW846 3510/8270

Aqueous samples, fortified with surrogates, are extracted using liquid/liquid extraction technique. The sample extracts are concentrated and then analyzed using GC/MS. Results for benzo(b) fluoranthene may include contributions from benzo(j)fluoranthene, if also present in the sample.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

PCB-511-WT Water PCB-O. Reg 153/04 (July 2011) SW846 3510/8082

Aqueous samples are extracted, then concentrated, reconstituted, and analyzed by GC/MS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C

VOC-511-HS-WT Water VOC by GCMS HS O.Reg 153/04 (July 2011) SW846 8260

Liquid samples are analyzed by headspace GC/MSD.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.
LCS-H	Lab Control Sample recovery was above ALS DQO. Non-detected sample results are considered reliable. Other results, if reported, have been qualified.
MES	Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

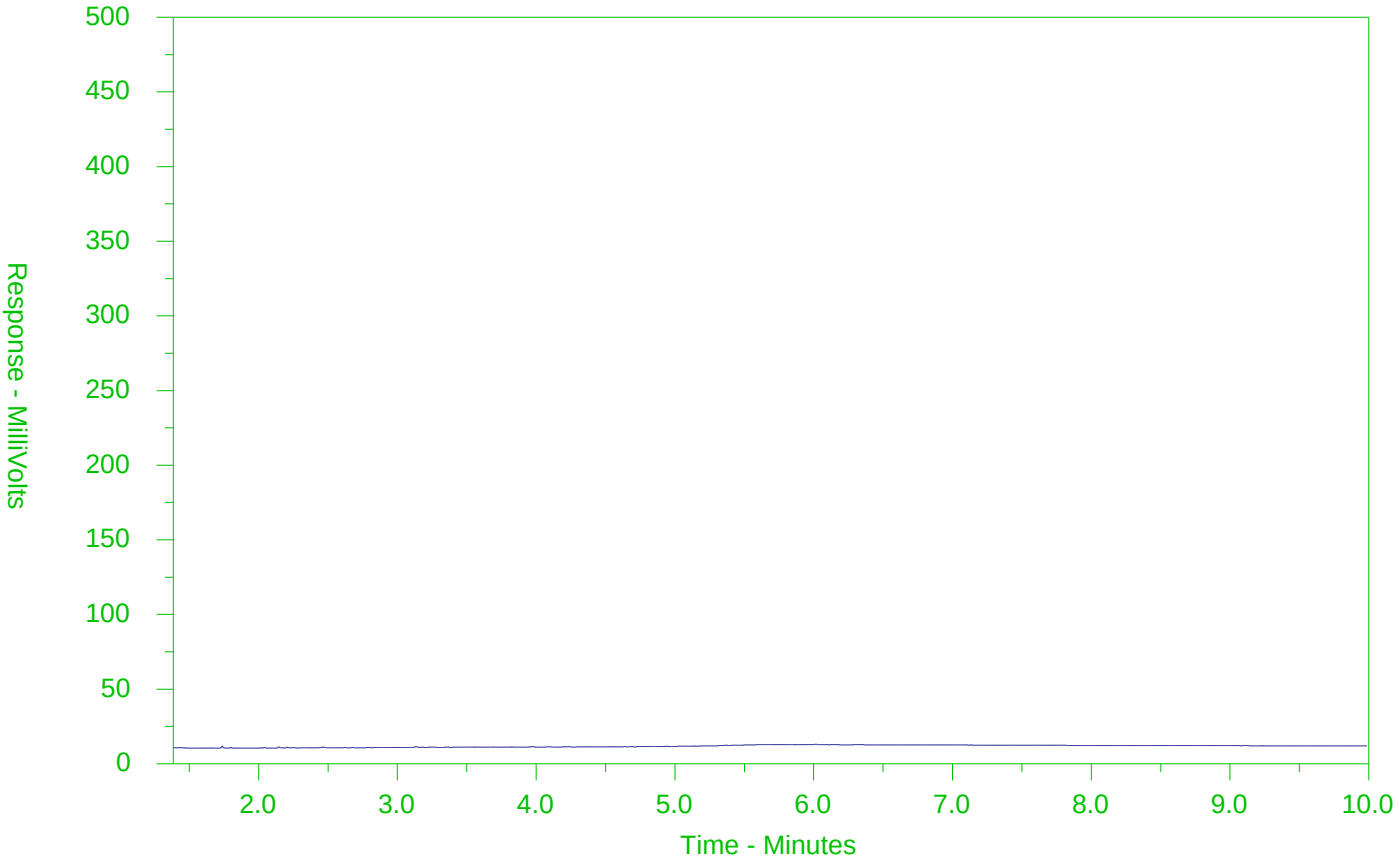
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2141576-8
Client Sample ID: MW18-126D



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C

Gasoline →	← Motor Oils/Lube Oils/Grease →		
←Diesel/Jet Fuels→			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

** Detection Limit for result exceeds Guideline Limit. Assessment against Guideline Limit cannot be made.
* Analytical result for this parameter exceeds Guideline Limit listed on this report. Guideline Limits applied:

T6-Ground Water-All Types of Property Uses

#1: T6-Ground Water-All Types of Property Uses

Reference Information

Sample Parameter Qualifier key listed:

Qualifier	Description
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
OWP	Organic water sample contained visible sediment (must be included as part of analysis). Measured concentrations of organic substances in water can be biased high due to presence of sediment.

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
BAP-LABFILTER-511-WT	Water	B(a)P-lab filtered-153/04 (July 2011)	SW846 8270 (511)

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

F1-F4-511-CALC-WT	Water	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-L

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT	Water	F1-O.Reg 153/04 (July 2011)	E3398/CCME TIER 1-HS

Fraction F1 is determined by analyzing by headspace-GC/FID.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F2-F4-511-WT	Water	F2-F4-O.Reg 153/04 (July 2011)	EPA 3511/CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from water using a hexane micro-extraction technique. Instrumental analysis is by GC-FID, as per the Reference Method for the Canada-Wide Standard for Petroleum Hydrocarbons in Soil Tier 1 Method, CCME, 2001.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

METHYLNAPS-CALC-WT	Water	PAH-Calculated Parameters	SW846 8270
PAH-511-WT	Water	PAH-O. Reg 153/04 (July 2011)	SW846 3510/8270

Aqueous samples, fortified with surrogates, are extracted using liquid/liquid extraction technique. The sample extracts are concentrated and then analyzed using GC/MS. Results for benzo(b) fluoranthene may include contributions from benzo(j)fluoranthene, if also present in the sample.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260

Liquid samples are analyzed by headspace GC/MSD.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

Reference Information

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

17-728110

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Application of guidelines is provided "as is" without warranty of any kind, either expressed or implied, including, but not limited to, fitness for a particular purpose, or non-infringement. ALS assumes no responsibility for errors or omissions in the information. Guideline limits are not adjusted for the hardness, pH or temperature of the sample (the most conservative values are used). Measurement uncertainty is not applied to test results prior to comparison with specified criteria values.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
MES	Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

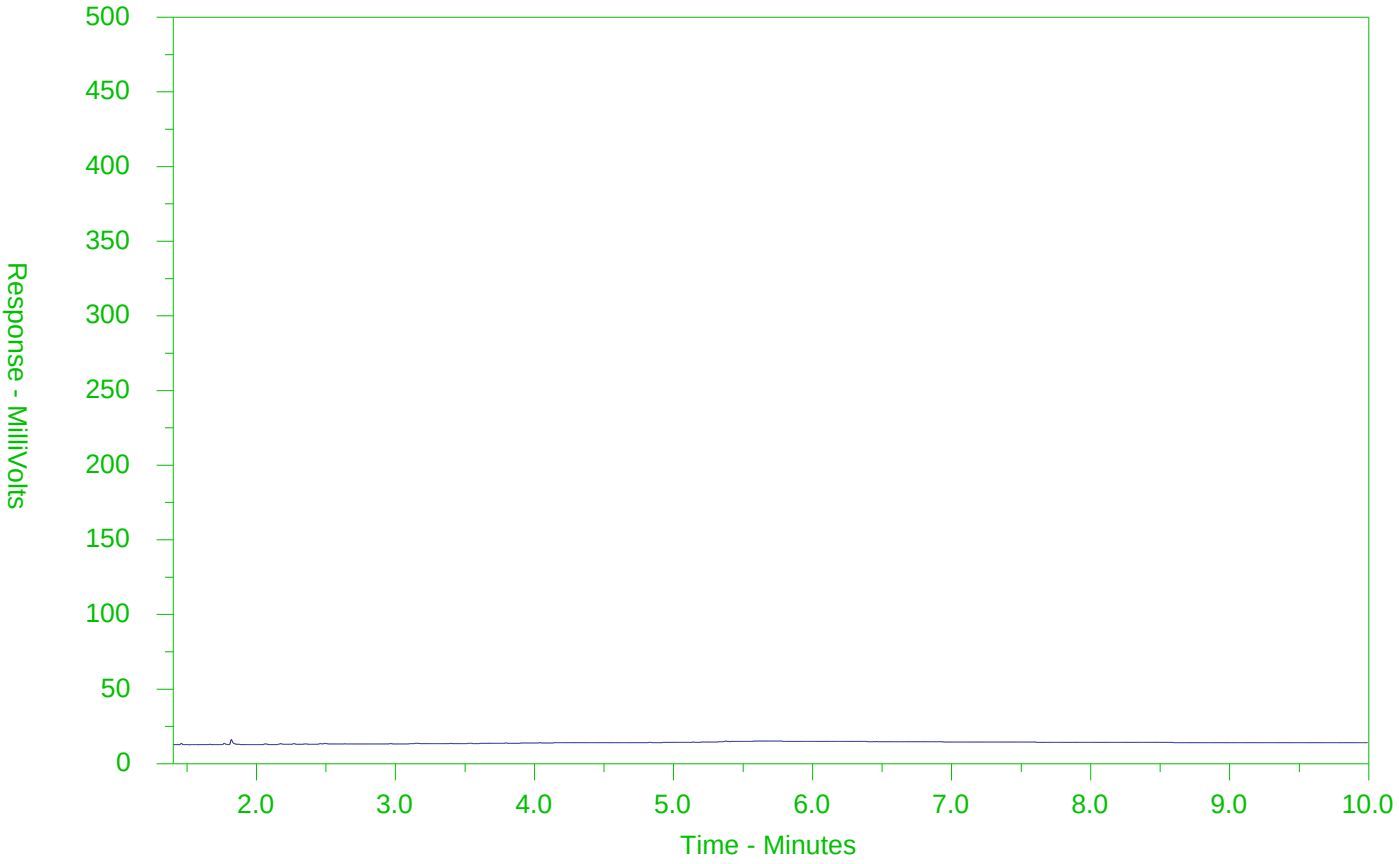
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2182846-6
Client Sample ID: MW18-130D



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C
346°F	549°F	898°F	1067°F
Gasoline →	← Motor Oils/Lube Oils/Grease →		
← Diesel/Jet Fuels →			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

Reference Information

Sample Parameter Qualifier key listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
MET-D-UG/L-MS-WT	Water	Diss. Metals in Water by ICPMS (ug/L)	EPA 200.8

The metal constituents of a non-acidified sample that pass through a membrane filter prior to ICP/MS analysis.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260

Liquid samples are analyzed by headspace GC/MSD.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

17-728707

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Laboratory Control Sample	Dichlorodifluoromethane	LCS-H	L2203734-1, -2
Laboratory Control Sample	Trichlorofluoromethane	MES	L2203734-1, -2

Qualifiers for Sample Submission Listed:

Qualifier	Description
CINT	Cooling initiated. Samples were received packed with ice or ice packs and were sampled the same day as received.

Sample Parameter Qualifier key listed:

Qualifier	Description
LCS-H	Lab Control Sample recovery was above ALS DQO. Non-detected sample results are considered reliable. Other results, if reported, have been qualified.
MES	Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260

Liquid samples are analyzed by headspace GC/MSD.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

17-728964

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
LCS-H	Lab Control Sample recovery was above ALS DQO. Non-detected sample results are considered reliable. Other results, if reported, have been qualified.
MES	Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

Sample Parameter Qualifier key listed:

Qualifier	Description
PEHT	Parameter Exceeded Recommended Holding Time Prior to Analysis

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
THM-SUM-PPB-CALC-WT	Water	Total Trihalomethanes (THMs)	CALCULATION
Total Trihalomethanes (THMs) represents the sum of bromodichloromethane, bromoform, chlorodibromomethane and chloroform. For the purpose of calculation, results less than the detection limit (DL) are treated as zero.			
VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260
Liquid samples are analyzed by headspace GC/MSD.			
Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).			
VOC-ROU-HS-WT	Water	Volatile Organic Compounds	SW846 8260
Aqueous samples are analyzed by headspace-GC/MS.			
XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION
Total xylenes represents the sum of o-xylene and m&p-xylene.			

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

17-666267

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend & Qualifier Definitions:

EHTR-FM: Exceeded ALS recommended hold time prior to sample receipt. Field Measurement recommended.
EHTR: Exceeded ALS recommended hold time prior to sample receipt.
EHTL: Exceeded ALS recommended hold time prior to analysis. Sample was received less than 24 hours prior to expiry.
EHT: Exceeded ALS recommended hold time prior to analysis.
Rec. HT: ALS recommended hold time (see units).

Notes*:
Where actual sampling date is not provided to ALS, the date (& time) of receipt is used for calculation purposes.
Where actual sampling time is not provided to ALS, the earlier of 12 noon on the sampling date or the time (& date) of receipt is used for calculation purposes. Samples for L2204937 were received on 03-DEC-18 17:35.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Physical Tests							
pH	7.78		0.10	pH units		05-DEC-18	R4374328

* Refer to Referenced Information for Qualifiers (if any) and Methodology.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
PH-WT	Soil	pH	MOEE E3137A

A minimum 10g portion of the sample is extracted with 20mL of 0.01M calcium chloride solution by shaking for at least 30 minutes. The aqueous layer is separated from the soil and then analyzed using a pH meter and electrode.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

17-666268

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

** Detection Limit for result exceeds Guideline Limit. Assessment against Guideline Limit cannot be made.
* Analytical result for this parameter exceeds Guideline Limit listed on this report. Guideline Limits applied:

T6-Ground Water-All Types of Property Uses

#1: T6-Ground Water-All Types of Property Uses

Reference Information

Sample Parameter Qualifier key listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
MET-D-UG/L-MS-WT	Water	Diss. Metals in Water by ICPMS (ug/L)	EPA 200.8

The metal constituents of a non-acidified sample that pass through a membrane filter prior to ICP/MS analysis.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260

Liquid samples are analyzed by headspace GC/MSD.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

17-20181212

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
MES	Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

Sample Parameter Qualifier key listed:

Qualifier	Description
DLQ	Detection Limit raised due to co-eluting interference. GCMS qualifier ion ratio did not meet acceptance criteria.
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
F1-F4-511-CALC-WT	Water	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-L

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT	Water	F1-O.Reg 153/04 (July 2011)	E3398/CCME TIER 1-HS

Fraction F1 is determined by analyzing by headspace-GC/FID.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F2-F4-511-WT	Water	F2-F4-O.Reg 153/04 (July 2011)	EPA 3511/CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from water using a hexane micro-extraction technique. Instrumental analysis is by GC-FID, as per the Reference Method for the Canada-Wide Standard for Petroleum Hydrocarbons in Soil Tier 1 Method, CCME, 2001.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

MET-D-UG/L-MS-WT	Water	Diss. Metals in Water by ICPMS (ug/L)	EPA 200.8

The metal constituents of a non-acidified sample that pass through a membrane filter prior to ICP/MS analysis.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

METHYLNAPS-CALC-WT	Water	PAH-Calculated Parameters	SW846 8270
PAH-511-WT	Water	PAH-O. Reg 153/04 (July 2011)	SW846 3510/8270

Aqueous samples, fortified with surrogates, are extracted using liquid/liquid extraction technique. The sample extracts are concentrated and then analyzed using GC/MS. Results for benzo(b) fluoranthene may include contributions from benzo(j)fluoranthene, if also present in the sample.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260

Liquid samples are analyzed by headspace GC/MSD.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

Reference Information

XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

17-12122018

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Application of guidelines is provided "as is" without warranty of any kind, either expressed or implied, including, but not limited to, fitness for a particular purpose, or non-infringement. ALS assumes no responsibility for errors or omissions in the information. Guideline limits are not adjusted for the hardness, pH or temperature of the sample (the most conservative values are used). Measurement uncertainty is not applied to test results prior to comparison with specified criteria values.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
MES	Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

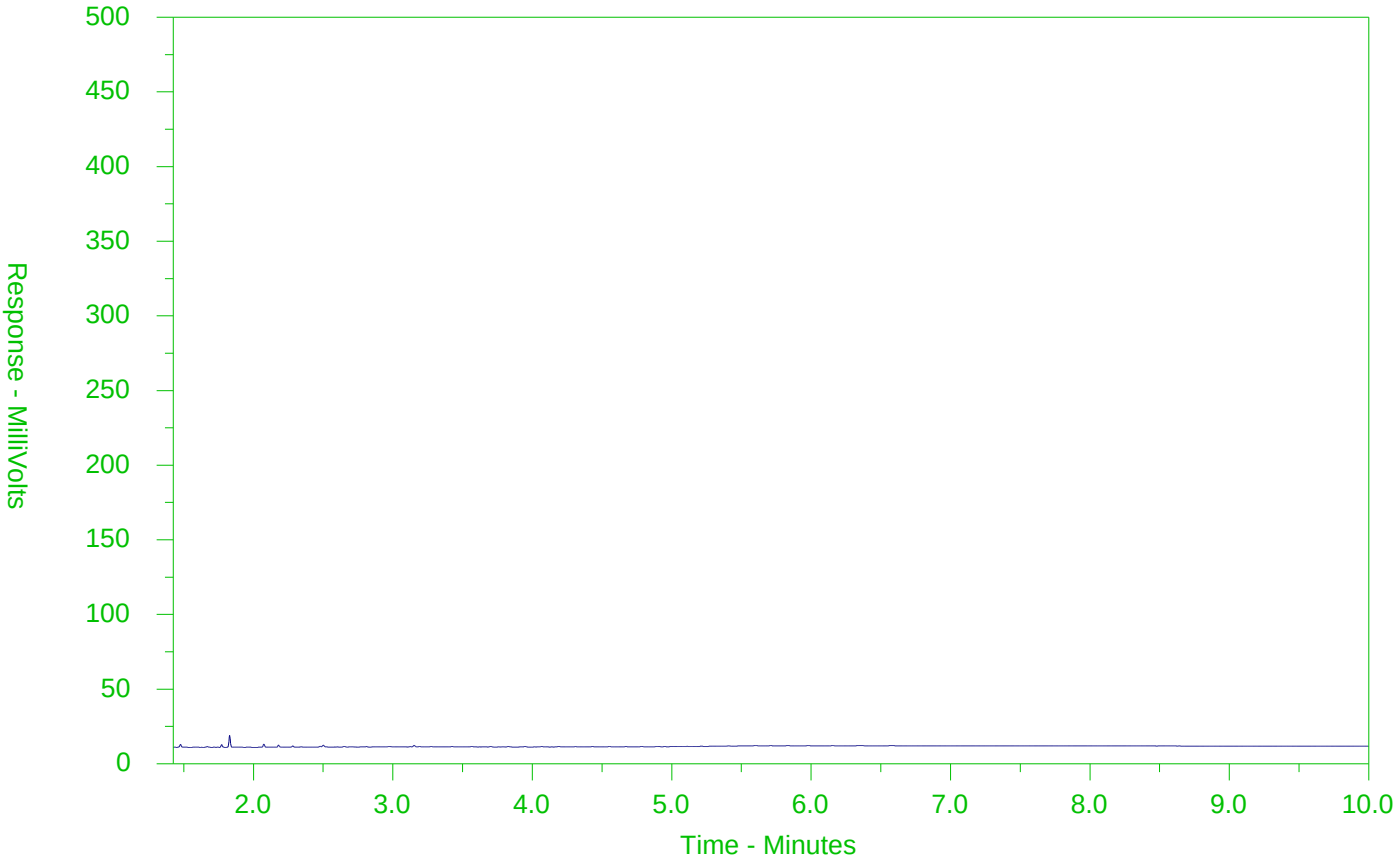
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2209758-7
Client Sample ID: MW18-135D



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C
346°F	549°F	898°F	1067°F
Gasoline →		← Motor Oils/Lube Oils/Grease →	
← Diesel/Jet Fuels →			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

* Refer to Referenced Information for Qualifiers (if any) and Methodology.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
MET-D-CCMS-WT	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

17-625974

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Matrix Spike	Barium (Ba)-Dissolved	MS-B	L2213740-4
Matrix Spike	Boron (B)-Dissolved	MS-B	L2213740-4
Matrix Spike	Uranium (U)-Dissolved	MS-B	L2213740-4

Sample Parameter Qualifier key listed:

Qualifier	Description
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
BTX-511-HS-WT	Water	BTEX by Headspace	SW846 8260 (511)
BTX is determined by analyzing by headspace-GC/MS.			
MET-D-UG/L-MS-WT	Water	Diss. Metals in Water by ICPMS (ug/L)	EPA 200.8
The metal constituents of a non-acidified sample that pass through a membrane filter prior to ICP/MS analysis.			
Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).			
VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260
Liquid samples are analyzed by headspace GC/MSD.			
Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).			
XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION
Total xylenes represents the sum of o-xylene and m&p-xylene.			

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

17-641726

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Quality Control Report

Workorder: L2213740 Report Date: 28-DEC-18

Client: CH2M HILL Canada Ltd.
245 CONSUMERS ROAD, SUITE 400
TORONTO ON M2J 1R3
Contact: MICHAEL SHIRY

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Matrix Spike	Barium (Ba)-Dissolved	MS-B	L2250326-10, -3
Matrix Spike	Boron (B)-Dissolved	MS-B	L2250326-10, -3
Matrix Spike	Sodium (Na)-Dissolved	MS-B	L2250326-10, -3
Matrix Spike	Uranium (U)-Dissolved	MS-B	L2250326-10, -3

Sample Parameter Qualifier key listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
BAP-LABFILTER-511-WT	Water	B(a)P-lab filtered-153/04 (July 2011)	SW846 8270 (511)

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

F1-F4-511-CALC-WT	Water	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-L

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT	Water	F1-O.Reg 153/04 (July 2011)	E3398/CCME TIER 1-HS

Fraction F1 is determined by analyzing by headspace-GC/FID.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F2-F4-511-WT	Water	F2-F4-O.Reg 153/04 (July 2011)	EPA 3511/CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from water using a hexane micro-extraction technique. Instrumental analysis is by GC-FID, as per the Reference Method for the Canada-Wide Standard for Petroleum Hydrocarbons in Soil Tier 1 Method, CCME, 2001.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

MET-D-UG/L-MS-WT	Water	Diss. Metals in Water by ICPMS (ug/L)	EPA 200.8

The metal constituents of a non-acidified sample that pass through a membrane filter prior to ICP/MS analysis.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

METHYLNAPS-CALC-WT	Water	PAH-Calculated Parameters	SW846 8270

PAH-511-WT	Water	PAH-O. Reg 153/04 (July 2011)	SW846 3510/8270

Aqueous samples, fortified with surrogates, are extracted using liquid/liquid extraction technique. The sample extracts are concentrated and then analyzed using GC/MS. Results for benzo(b) fluoranthene may include contributions from benzo(j)fluoranthene, if also present in the sample.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG

Reference Information

must be reported).

PCB-511-WT Water PCB-O. Reg 153/04 (July 2011) SW846 3510/8082
Aqueous samples are extracted, then concentrated, reconstituted, and analyzed by GC/MS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

17-623248 17-728869

GLOSSARY OF REPORT TERMS
Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

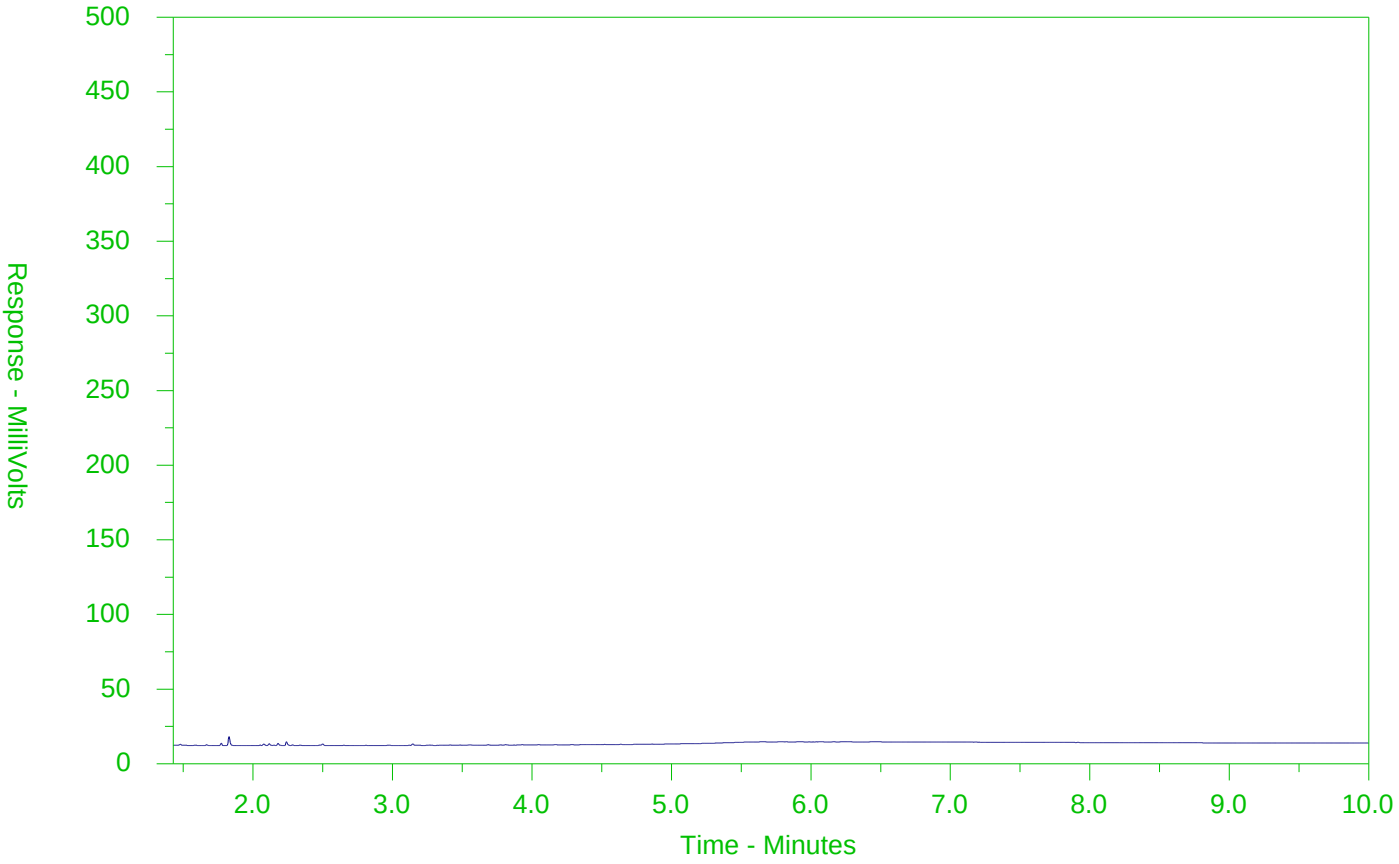
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2250326-1
Client Sample ID: OW25



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C
346°F	549°F	898°F	1067°F
Gasoline →		← Motor Oils/Lube Oils/Grease →	
← Diesel/Jet Fuels →			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
MOISTURE-WT	Soil	% Moisture	CCME PHC in Soil - Tier 1 (mod)
PH-WT	Soil	pH	MOEE E3137A

A minimum 10g portion of the sample is extracted with 20mL of 0.01M calcium chloride solution by shaking for at least 30 minutes. The aqueous layer is separated from the soil and then analyzed using a pH meter and electrode.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

VOC-1,3-DCP-CALC-WT	Soil	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Soil	VOC-O.Reg 153/04 (July 2011)	SW846 8260 (511)

Soil and sediment samples are extracted in methanol and analyzed by headspace-GC/MS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Soil	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

17-630752

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Laboratory Control Sample	Vinyl chloride	MES	L2259873-1, -10, -11, -12, -2, -3, -4, -5, -6, -7, -8, -9

Sample Parameter Qualifier key listed:

Qualifier	Description
MES	Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
METHYLNAPS-CALC-WT	Water	PAH-Calculated Parameters	SW846 8270
MOISTURE-WT	Soil	% Moisture	CCME PHC in Soil - Tier 1 (mod)
PAH-511-WT	Water	PAH-O. Reg 153/04 (July 2011)	SW846 3510/8270

Aqueous samples, fortified with surrogates, are extracted using liquid/liquid extraction technique. The sample extracts are concentrated and then analyzed using GC/MS. Results for benzo(b) fluoranthene may include contributions from benzo(j)fluoranthene, if also present in the sample.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

VOC-1,3-DCP-CALC-WT	Soil	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Soil	VOC-O.Reg 153/04 (July 2011)	SW846 8260 (511)

Soil and sediment samples are extracted in methanol and analyzed by headspace-GC/MS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Soil	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

17-622539 17-623582

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Client: CH2M HILL CANADA LIMITED
72 VICTORIA ST S, SUITE 300
KITCHENER ON N2G 4Y9
Contact: JON GOWING

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
MES	Data Quality Objective was marginally exceeded (by < 10% absolute) for < 10% of analytes in a Multi-Element Scan / Multi-Parameter Scan (considered acceptable as per OMOE & CCME).
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Laboratory Control Sample	3,3'-Dichlorobenzidine	LCS-L	L2419793-13

Sample Parameter Qualifier key listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).
DLVH	Detection Limit raised due to interference from Volatile Hydrocarbons on VOC method. Chromatographic elution of interfering peaks in the same region as test analytes prevents a determination of whether VOC analyte is present or absent (above/below regular detection limits).
LCS-L	Lab Control Sample recovery was below ALS DQO. Reference Material and/or Matrix Spike results were acceptable. Non-detected sample results are considered reliable. Other results, if reported, have been qualified.
RRR	Refer to Report Remarks for issues regarding this analysis
SAR:DL	SAR is incalculable due to undetectable Na. Detection Limit represents maximum possible SAR value.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
625-511-WT	Soil	ABN-O.Reg 153/04 (July 2011)	SW846 8270 (511)

Soil and sediment samples are dried by mixing with a desiccant prior to extraction. The extracts are dried, concentrated and exchanged into a solvent and analyzed by GC/MS. Depending on the analytical GC/MS column used benzo(j)fluoranthene may chromatographically co-elute with benzo(b)fluoranthene or benzo(k)fluoranthene.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

B-HWS-R511-WT	Soil	Boron-HWE-O.Reg 153/04 (July 2011)	HW EXTR, EPA 6010B

A dried solid sample is extracted with calcium chloride, the sample undergoes a heating process. After cooling the sample is filtered and analyzed by ICP/OES.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

CN-WAD-R511-WT	Soil	Cyanide (WAD)-O.Reg 153/04 (July 2011)	MOE 3015/APHA 4500CN I-WAD

The sample is extracted with a strong base for 16 hours, and then filtered. The filtrate is then distilled where the cyanide is converted to cyanogen chloride by reacting with chloramine-T, the cyanogen chloride then reacts with a combination of barbituric acid and isonicotinic acid to form a highly colored complex.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

CR-CR6-IC-WT	Soil	Hexavalent Chromium in Soil	SW846 3060A/7199

This analysis is carried out using procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846, Method 7199, published by the United States Environmental Protection Agency (EPA). The procedure involves analysis for chromium (VI) by ion chromatography using diphenylcarbazide in a sulphuric acid solution.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

DINITROTOL-CALC-WT	Soil	ABN-Calculated Parameters	SW846 8270
EC-WT	Soil	Conductivity (EC)	MOEE E3138

A representative subsample is tumbled with de-ionized (DI) water. The ratio of water to soil is 2:1 v/w. After tumbling the sample is then analyzed by a conductivity meter.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

F1-F4-511-CALC-WT	Soil	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-S

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

Hydrocarbon results are expressed on a dry weight basis.

Reference Information

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT Soil F1-O.Reg 153/04 (July 2011) E3398/CCME TIER 1-HS

Fraction F1 is determined by extracting a soil or sediment sample as received with methanol, then analyzing by headspace-GC/FID.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F2-F4-511-WT Soil F2-F4-O.Reg 153/04 (July 2011) CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from soil with 1:1 hexane:acetone using a rotary extractor. Extracts are treated with silica gel to remove polar organic interferences. F2, F3, & F4 are analyzed by GC-FID. F4G-sg is analyzed gravimetrically.

Notes:
1. F2 (C10-C16): Sum of all hydrocarbons that elute between nC10 and nC16.
2. F3 (C16-C34): Sum of all hydrocarbons that elute between nC16 and nC34.
3. F4 (C34-C50): Sum of all hydrocarbons that elute between nC34 and nC50.
4. F4G: Gravimetric Heavy Hydrocarbons
5. F4G-sg: Gravimetric Heavy Hydrocarbons (F4G) after silica gel treatment.
6. Where both F4 (C34-C50) and F4G-sg are reported for a sample, the larger of the two values is used for comparison against the relevant CCME guideline for F4.
7. F4G-sg cannot be added to the C6 to C50 hydrocarbon results to obtain an estimate of total extractable hydrocarbons.
8. This method is validated for use.
9. Data from analysis of validation and quality control samples is available upon request.
10. Reported results are expressed as milligrams per dry kilogram, unless otherwise indicated.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F4G-ADD-511-WT Soil F4G SG-O.Reg 153/04 (July 2011) MOE DECPH-E3398/CCME TIER 1

F4G, gravimetric analysis, is determined if the chromatogram does not return to baseline at or before C50. A soil sample is extracted with a solvent mix, the solvent is evaporated and the weight of the residue is determined.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

HG-200.2-CVAA-WT Soil Mercury in Soil by CVAAS EPA 200.2/1631E (mod)

Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAAS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

MET-200.2-CCMS-WT Soil Metals in Soil by CRC ICPMS EPA 200.2/6020B (mod)

Soil/sediment is dried, disaggregated, and sieved (2 mm). For tests intended to support Ontario regulations, the <2mm fraction is ground to pass through a 0.355 mm sieve. Strong Acid Leachable Metals in the <2mm fraction are solubilized by heated digestion with nitric and hydrochloric acids. Instrumental analysis is by Collision / Reaction Cell ICPMS.

Limitations: This method is intended to liberate environmentally available metals. Silicate minerals are not solubilized. Some metals may be only partially recovered (matrix dependent), including Al, Ba, Be, Cr, S, Sr, Ti, Tl, V, W, and Zr. Elemental Sulfur may be poorly recovered by this method. Volatile forms of sulfur (e.g. sulfide, H2S) may be excluded if lost during sampling, storage, or digestion.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG

Reference Information

must be reported).

METHYLNAPS-CALC-WT	Soil	ABN-Calculated Parameters	SW846 8270
MOISTURE-WT	Soil	% Moisture	CCME PHC in Soil - Tier 1 (mod)
PAH-511-WT	Soil	PAH-O.Reg 153/04 (July 2011)	SW846 3510/8270

A representative sub-sample of soil is fortified with deuterium-labelled surrogates and a mechanical shaking techniqueis used to extract the sample with a mixture of methanol and toluene. The extracts are concentrated and analyzed by GC/MS. Results for benzo(b) fluoranthene may include contributions from benzo(j)fluoranthene, if also present in the sample.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

SAR-R511-WT	Soil	SAR-O.Reg 153/04 (July 2011)	SW846 6010C

A dried, disaggregated solid sample is extracted with deionized water, the aqueous extract is separated from the solid, acidified and then analyzed using a ICP/OES. The concentrations of Na, Ca and Mg are reported as per CALA requirements for calculated parameters. These individual parameters are not for comparison to any guideline.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

VOC-1,3-DCP-CALC-WT	Soil	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Soil	VOC-O.Reg 153/04 (July 2011)	SW846 8260 (511)

Soil and sediment samples are extracted in methanol and analyzed by headspace-GC/MS.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Soil	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

17-795231

Reference Information

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
J	Duplicate results and limits are expressed in terms of absolute difference.
LCS-L	Lab Control Sample recovery was below ALS DQO. Reference Material and/or Matrix Spike results were acceptable. Non-detected sample results are considered reliable. Other results, if reported, have been qualified.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.
SURQC	Surrogate recovery marginally exceeded DQO in QC sample (MB, LCS, RM, or MS). Surrogates are less important for QC samples than for test samples. Refer to regular (non-surrogate) analyte results in affected QC sample for assessment of potential impacts to those analytes.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2419793-1
Client Sample ID: TP20-324-1-1.5'

← Diesel/Jet Fuels →			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

T1-Ground Water-All Types of Property Uses

#1: T1-Ground Water-All Types of Property Uses

Reference Information

Sample Parameter Qualifier key listed:

Qualifier	Description
DLQ	Detection Limit raised due to co-eluting interference. GCMS qualifier ion ratio did not meet acceptance criteria.

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
625-511-WT	Water	ABN,CP,PAH-O.Reg 153/04	SW846 8270 (511)

Ground water sample extraction is carried out at a pH <2 (acid extractables) and pH>11 (base neutral extractables). Extracts are dried, concentrated and exchanged into a solvent compatible with the cleanup. Analysis is by GC/MS. Depending on the analytical GC/MS column used benzo(j)fluoranthene may chromatographically co-elute with benzo(b)fluoranthene or benzo(k)fluoranthene.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

DINITROTOL-CALC-WT	Water	ABN-Calculated Parameters	SW846 8270
F1-F4-511-CALC-WT	Water	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-L

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT	Water	F1-O.Reg 153/04 (July 2011)	E3398/CCME TIER 1-HS

Fraction F1 is determined by analyzing by headspace-GC/FID.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F2-F4-511-WT	Water	F2-F4-O.Reg 153/04 (July 2011)	EPA 3511/CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from water using a hexane micro-extraction technique. Instrumental analysis is by GC-FID, as per the Reference Method for the Canada-Wide Standard for Petroleum Hydrocarbons in Soil Tier 1 Method, CCME, 2001.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

METHYLNAPS-CALC-WT	Water	PAH-Calculated Parameters	SW846 8270
PAH-511-WT	Water	PAH-O. Reg 153/04 (July 2011)	SW846 3510/8270

Aqueous samples, fortified with surrogates, are extracted using liquid/liquid extraction technique. The sample extracts are concentrated and then analyzed using GC/MS. Results for benzo(b) fluoranthene may include contributions from benzo(j)fluoranthene, if also present in the sample.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260

Liquid samples are analyzed by headspace GC/MSD.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

Reference Information

XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

17-795244 17-795253 17-795254

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.
RRQC	Refer to report remarks for information regarding this QC result.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

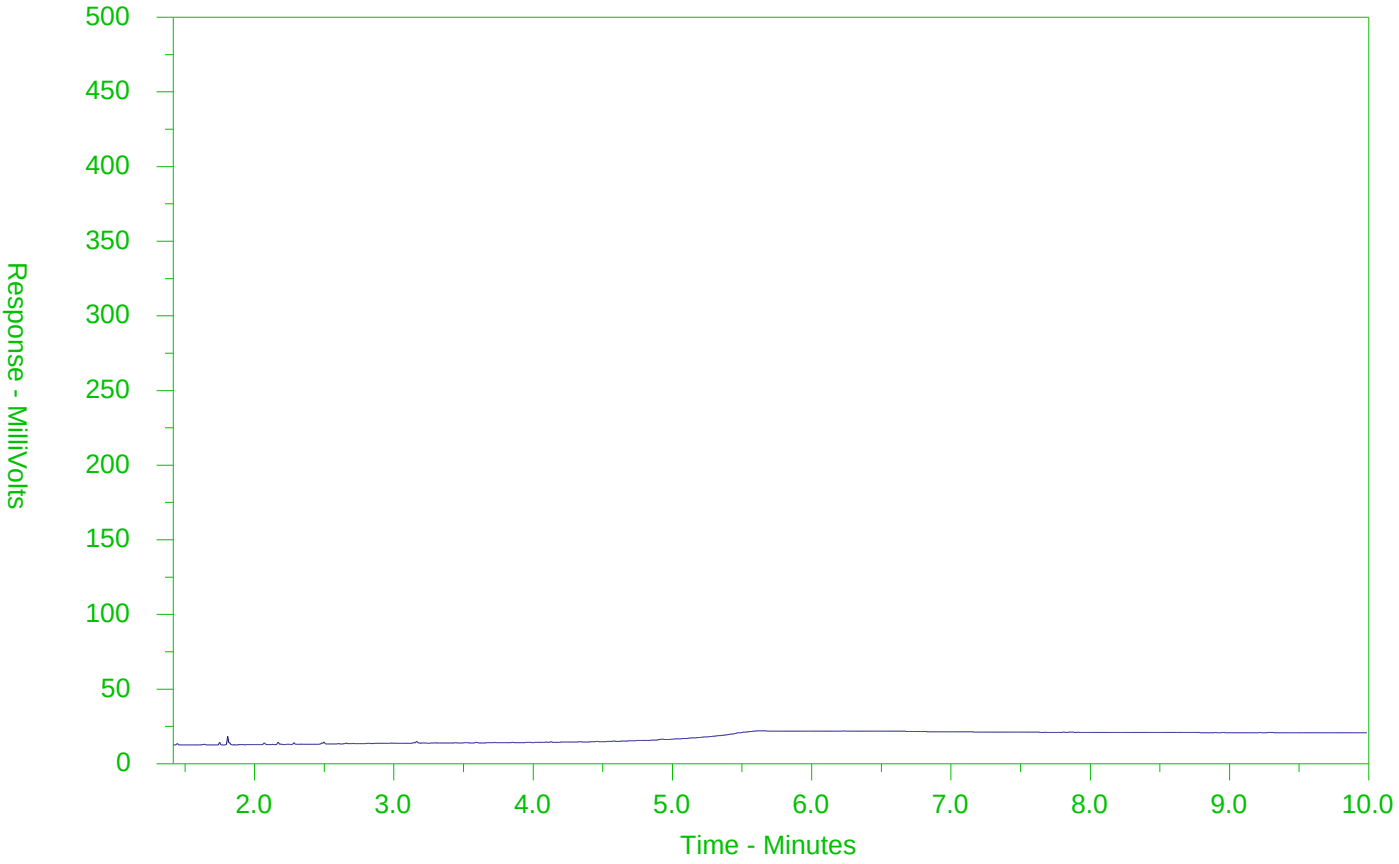
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2420861-1
Client Sample ID: MW18-115S



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C
346°F	549°F	898°F	1067°F
Gasoline →	← Motor Oils/Lube Oils/Grease →		
← Diesel/Jet Fuels →			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

T1-Ground Water-All Types of Property Uses

#1: T1-Ground Water-All Types of Property Uses

Reference Information

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
F1-F4-511-CALC-WT	Water	F1-F4 Hydrocarbon Calculated Parameters	CCME CWS-PHC, Pub #1310, Dec 2001-L

Analytical methods used for analysis of CCME Petroleum Hydrocarbons have been validated and comply with the Reference Method for the CWS PHC.

In cases where results for both F4 and F4G are reported, the greater of the two results must be used in any application of the CWS PHC guidelines and the gravimetric heavy hydrocarbons cannot be added to the C6 to C50 hydrocarbons.
In samples where BTEX and F1 were analyzed , F1-BTEX represents a value where the sum of Benzene, Toluene, Ethylbenzene and total Xylenes has been subtracted from F1.

In samples where PAHs, F2 and F3 were analyzed, F2-Naphth represents the result where Naphthalene has been subtracted from F2. F3-PAH represents a result where the sum of Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, Fluoranthene, Indeno(1,2,3-cd)pyrene, Phenanthrene, and Pyrene has been subtracted from F3.

Unless otherwise qualified, the following quality control criteria have been met for the F1 hydrocarbon range:
1. All extraction and analysis holding times were met.
2. Instrument performance showing response factors for C6 and C10 within 30% of the response factor for toluene.
3. Linearity of gasoline response within 15% throughout the calibration range.

Unless otherwise qualified, the following quality control criteria have been met for the F2-F4 hydrocarbon ranges:
1. All extraction and analysis holding times were met.
2. Instrument performance showing C10, C16 and C34 response factors within 10% of their average.
3. Instrument performance showing the C50 response factor within 30% of the average of the C10, C16 and C34 response factors.
4. Linearity of diesel or motor oil response within 15% throughout the calibration range.

F1-HS-511-WT	Water	F1-O.Reg 153/04 (July 2011)	E3398/CCME TIER 1-HS

Fraction F1 is determined by analyzing by headspace-GC/FID.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

F2-F4-511-WT	Water	F2-F4-O.Reg 153/04 (July 2011)	EPA 3511/CCME Tier 1

Petroleum Hydrocarbons (F2-F4 fractions) are extracted from water using a hexane micro-extraction technique. Instrumental analysis is by GC-FID, as per the Reference Method for the Canada-Wide Standard for Petroleum Hydrocarbons in Soil Tier 1 Method, CCME, 2001.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260

Liquid samples are analyzed by headspace GC/MSD.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

17-795245 17-795246 17-795247 17-795248

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

Reference Information

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Application of guidelines is provided "as is" without warranty of any kind, either expressed or implied, including, but not limited to, fitness for a particular purpose, or non-infringement. ALS assumes no responsibility for errors or omissions in the information. Guideline limits are not adjusted for the hardness, pH or temperature of the sample (the most conservative values are used). Measurement uncertainty is not applied to test results prior to comparison with specified criteria values.

Quality Control Report

Workorder: L2422349 Report Date: 04-MAR-20

Client: CH2M HILL CANADA LIMITED
72 VICTORIA ST S, SUITE 300
KITCHENER ON N2G 4Y9
Contact: Michael Shiry

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

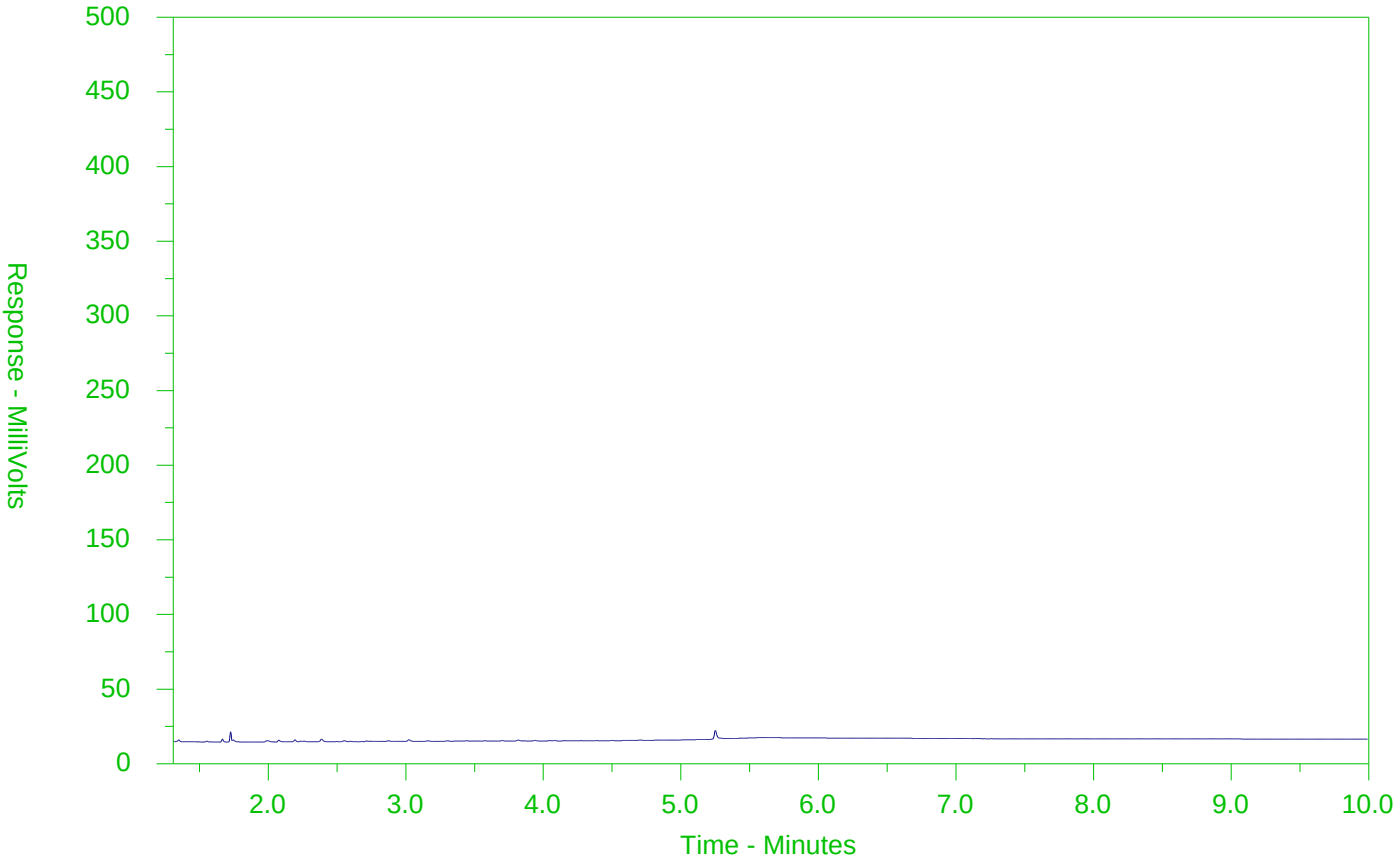
ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

CCME F2-F4 HYDROCARBON DISTRIBUTION REPORT

ALS Sample ID: L2422349-19
Client Sample ID: MW19-137S



←F2→	←F3→	←F4→	
nC10	nC16	nC34	nC50
174°C	287°C	481°C	575°C
346°F	549°F	898°F	1067°F
Gasoline →		← Motor Oils/Lube Oils/Grease →	
← Diesel/Jet Fuels →			

The CCME F2-F4 Hydrocarbon Distribution Report (HDR) is intended to assist you in characterizing hydrocarbon products that may be present in your sample.

The scale at the bottom of the chromatogram indicates the approximate retention times of common petroleum products and four n-alkane hydrocarbon marker compounds. Retention times may vary between samples, but general patterns and distributions will remain similar.

Peak heights in this report are a function of the sample concentration, the sample amount extracted, the sample dilution factor and the scale at the left.

Note: This chromatogram was produced using GC conditions that are specific to ALS Canada CCME F2-F4 method. Refer to the ALS Canada CCME F2-F4 Hydrocarbon Library for a collection of chromatograms from common reference samples (fuels, oils, etc.). The HDR Library can be found at www.alsglobal.com.

T1-Ground Water-All Types of Property Uses

#1: T1-Ground Water-All Types of Property Uses

Reference Information

Sample Parameter Qualifier key listed:

Qualifier	Description
DLQ	Detection Limit raised due to co-eluting interference. GCMS qualifier ion ratio did not meet acceptance criteria.
OWP	Organic water sample contained visible sediment (must be included as part of analysis). Measured concentrations of organic substances in water can be biased high due to presence of sediment.
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260

Liquid samples are analyzed by headspace GC/MSD.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

17-795249 17-795250 17-795251

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

** Detection Limit for result exceeds Guideline Limit. Assessment against Guideline Limit cannot be made.
* Analytical result for this parameter exceeds Guideline Limit listed on this report. Guideline Limits applied:

T1-Ground Water-All Types of Property Uses

#1: T1-Ground Water-All Types of Property Uses

Reference Information

Methods Listed (if applicable):

ALS Test Code	Matrix	Test Description	Method Reference***
VOC-1,3-DCP-CALC-WT	Water	Regulation 153 VOCs	SW8260B/SW8270C
VOC-511-HS-WT	Water	VOC by GCMS HS O.Reg 153/04 (July 2011)	SW846 8260

Liquid samples are analyzed by headspace GC/MSD.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011), unless a subset of the Analytical Test Group (ATG) has been requested (the Protocol states that all analytes in an ATG must be reported).

XYLENES-SUM-CALC-WT	Water	Sum of Xylene Isomer Concentrations	CALCULATION

Total xylenes represents the sum of o-xylene and m&p-xylene.

*** ALS test methods may incorporate modifications from specified reference methods to improve performance.

Chain of Custody numbers:

17-795252

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location	Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA		

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Application of guidelines is provided "as is" without warranty of any kind, either expressed or implied, including, but not limited to, fitness for a particular purpose, or non-infringement. ALS assumes no responsibility for errors or omissions in the information. Guideline limits are not adjusted for the hardness, pH or temperature of the sample (the most conservative values are used). Measurement uncertainty is not applied to test results prior to comparison with specified criteria values.

Sample Parameter Qualifier Definitions:

Qualifier	Description
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Screening Tables

Appendix F1
Screening Tables

Table F1-1. Summary of COC Screening in Soil
Risk Assessment, 200 Beverley Street, Guelph, Ontario

Contaminant [a]	No. of Stations	No. of Samples	Max Detected Concentration	Max Nondetect Concentration	Maximum Measured Concentration b	Units	Applicable SCS [c]	Other Screening Value [d,e]	No. of Detects Exceeding Table 6 SCS	No. of Nondetects exceeding Table 6 SCS	Retained as a Contaminant for Risk Assessment? (Rationale)
2-(1-)Methylnaphthalene	54	86	4.93	0.5	4.93	µg/g	0.99	--	9	--	Yes, included (Max > Table 6 SCS)
Acenaphthene	89	125	94	0.63	94	µg/g	7.9	--	1	--	Yes, included (Max > Table 6 SCS)
Acenaphthylene	89	125	1	2	2	µg/g	0.15	--	6	13	Yes, included (Max > Table 6 SCS)
Anthracene	89	125	160	0.5	160	µg/g	0.67	--	9	--	Yes, included (Max > Table 6 SCS)
Antimony	116	194	18.6	2	18.6	µg/g	7.5	--	3	--	Yes, included (Max > Table 6 SCS)
Arsenic	101	179	23	--	23	µg/g	18	--	3	--	Yes, included (Max > Table 6 SCS)
Benzene	90	146	0.26	0.1	0.26	µg/g	0.21	--	3	--	Yes, included (Max > Table 6 SCS)
Benzo(a)anthracene	89	125	200	0.5	200	µg/g	0.5	--	21	--	Yes, included (Max > Table 6 SCS)
Benzo(a)pyrene	89	125	130	0.5	130	µg/g	0.3	--	26	7	Yes, included (Max > Table 6 SCS)
Benzo(b)fluoranthene	89	125	190	0.5	190	µg/g	0.78	--	16	--	Yes, included (Max > Table 6 SCS)
Benzo(g,h,i)perylene	89	125	70	0.5	70	µg/g	6.6	--	4	--	Yes, included (Max > Table 6 SCS)
Benzo(k)fluoranthene	89	125	66	0.5	66	µg/g	0.78	--	11	--	Yes, included (Max > Table 6 SCS)
Bismuth	61	103	150	1	150	µg/g	--	--	--	--	Yes, included (no standard available; detected results)
Cadmium	143	229	83.4	0.5	83.4	µg/g	1.2	--	68	--	Yes, included (Max > Table 6 SCS)
Calcium	89	135	220000	--	220000	µg/g	--	54000	80	--	Yes, included (Max > OTR value)
Chrysene	89	125	180	0.5	180	µg/g	7	--	5	--	Yes, included (Max > Table 6 SCS)
Cobalt	143	228	393	2	393	µg/g	22	--	2	--	Yes, included (Max > Table 6 SCS)
Copper	143	228	2460	--	2460	µg/g	140	--	6	--	Yes, included (Max > Table 6 SCS)
Dibenzo(a,h)anthracene	89	125	26	0.5	26	µg/g	0.1	--	21	13	Yes, included (Max > Table 6 SCS)
Electrical Conductivity	71	101	2.19	--	2.19	mS/cm	0.7	--	3	--	Yes, included (Max > Table 6 SCS; Retained for Ecological Health)[f]
Ethylbenzene	90	146	4.1	0.05	4.1	µg/g	1.1	--	1	--	Yes, included (Max > Table 6 SCS)
Fluoranthene	89	125	660	0.5	660	µg/g	0.69	--	24	--	Yes, included (Max > Table 6 SCS)
Fluorene	89	125	150	0.63	150	µg/g	62	--	1	--	Yes, included (Max > Table 6 SCS)
Indeno(1,2,3-Cd)Pyrene	89	125	80	0.5	80	µg/g	0.38	--	20	7	Yes, included (Max > Table 6 SCS)
Iron	89	135	128000	--	128000	µg/g	--	38000	26	--	Yes, included (Max > OTR value)
Lead	143	231	10100	--	10100	µg/g	120	--	76	--	Yes, included (Max > Table 6 SCS)
Magnesium	89	135	120000	--	120000	µg/g	--	17000	85	--	Yes, included (Max > OTR value)
Mercury	79	111	0.319	0.05	0.319	µg/g	0.27	--	1	--	Yes, included (Max > Table 6 SCS)
Molybdenum	140	229	35	3	35	µg/g	6.9	--	9	--	Yes, included (Max > Table 6 SCS)
Naphthalene	89	125	220	0.25	220	µg/g	0.6	--	11	--	Yes, included (Max > Table 6 SCS)
Nickel	143	228	117	2	117	µg/g	100	--	1	--	Yes, included (Max > Table 6 SCS)
PCB, Total	53	72	1.65	0.05	1.65	µg/g	0.35	--	6	--	Yes, included (Max > Table 6 SCS)
Petroleum Hydrocarbons F2 (C10-C16)	90	130	3600	50	3600	µg/g	98	--	4	--	Yes, included (Max > Table 6 SCS)
Petroleum Hydrocarbons F3 (C16-C34)	90	130	23000	50	23000	µg/g	300	--	27	--	Yes, included (Max > Table 6 SCS)
Petroleum Hydrocarbons F4 (C34-C50)	90	130	7300	50	7300	µg/g	2800	--	1	--	Yes, included (Max > Table 6 SCS)
Phenanthrene	89	125	900	0.46	900	µg/g	6.2	--	3	--	Yes, included (Max > Table 6 SCS)
Pyrene	89	125	470	0.5	470	µg/g	78	--	1	--	Yes, included (Max > Table 6 SCS)
Thallium	123	205	6	2	6	µg/g	1	--	4	23	Yes, included (Max > Table 6 SCS)
Trichloroethylene	79	126	35.4	0.05	35.4	µg/g	0.061	--	12	--	Yes, included (Max > Table 6 SCS)
Vanadium	136	221	100	0.3	100	µg/g	86	--	1	--	Yes, included (Max > Table 6 SCS)
Xylenes, Total	90	147	3.9	0.07	3.9	µg/g	3.1	--	1	--	Yes, included (Max > Table 6 SCS)
Zinc	143	230	67200	--	67200	µg/g	340	--	139	--	Yes, included (Max > Table 6 SCS)
1,1,1,2-Tetrachloroethane	79	126	--	0.05	0.05	µg/g	0.058	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,1,1-Trichloroethane	79	126	0.01	0.05	0.05	µg/g	0.38	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,1,2,2-Tetrachloroethane	79	125	--	0.05	0.05	µg/g	0.05	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,1,2-Trichloroethane	50	86	--	0.05	0.05	µg/g	0.05	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,1'-Biphenyl	13	21	0.237	0.25	0.25	µg/g	0.31	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,1-Dichloroethane	79	126	--	0.05	0.05	µg/g	0.47	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,1-Dichloroethene	79	126	--	0.05	0.05	µg/g	0.05	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,2,4-Trichlorobenzene	48	67	--	0.25	0.25	µg/g	0.36	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,2-Dibromoethane	79	126	--	0.05	0.05	µg/g	0.05	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,2-Dichlorobenzene	79	126	--	0.05	0.05	µg/g	1.2	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,2-Dichloroethane	79	126	--	0.05	0.05	µg/g	0.05	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,2-Dichloropropane	79	126	--	0.05	0.05	µg/g	0.05	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,3-Dichlorobenzene	79	126	--	0.05	0.05	µg/g	4.8	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,3-Dichloropropene	79	127	--	0.05	0.05	µg/g	0.05	--	--	--	No, excluded (Max < or = Table 6 SCS)
1,4-Dichlorobenzene	79	126	--	0.05	0.05	µg/g	0.083	--	--	--	No, excluded (Max < or = Table 6 SCS)

Table F1-1. Summary of COC Screening in Soil
Risk Assessment, 200 Beverley Street, Guelph, Ontario

Contaminant [a]	No. of Stations	No. of Samples	Max Detected Concentration	Max Nondetect Concentration	Maximum Measured Concentration b	Units	Applicable SCS [c]	Other Screening Value [d,e]	No. of Detects Exceeding Table 6 SCS	No. of Nondetects exceeding Table 6 SCS	Retained as a Contaminant for Risk Assessment? (Rationale)
1,4-Dioxane	2	3	--	0.2	0.2	µg/g	1.8	--	--	--	No, excluded (Max < or = Table 6 SCS)
2,4 & 2,6-Dinitrotoluene	19	21	--	0.35	0.35	µg/g	0.5	--	--	--	No, excluded (Max < or = Table 6 SCS)

Selenium	116	192	1.9	1	1.9	µg/g	2.4	--	--	--	No, excluded (Max < or = Table 6 SCS)
Silver	143	228	7.8	2	7.8	µg/g	20	--	--	--	No, excluded (Max < or = Table 6 SCS)
Sodium	72	96	210	100	210	µg/g	--	220	--	--	No, excluded (Max < or = OTR value)
Sodium Absorption Ratio	52	82	2	0.23	2	SAR	5	--	--	--	No, excluded (Max < or = Table 6 SCS)
Strontium	37	36	78.1	--	78.1	µg/g	--	87	--	--	No, excluded (Max < or = OTR value)
Styrene	79	126	--	0.05	0.05	µg/g	0.7	--	--	--	No, excluded (Max < or = Table 6 SCS)
Tetrachloroethene	79	126	--	0.05	0.05	µg/g	0.28	--	--	--	No, excluded (Max < or = Table 6 SCS)
Tin	10	12	9.6	5	9.6	µg/g	--	5 - 9.2 [e]	--	--	No, excluded (Max Considered within Background Range) [e]
Titanium	27	31	532	--	532	µg/g	--	5400	--	--	No, excluded (Max < or = OTR value)
Toluene	90	146	1.2	0.08	1.2	µg/g	2.3	--	--	--	No, excluded (Max < or = Table 6 SCS)
trans-1,2-Dichloroethene	79	126	--	0.05	0.05	µg/g	0.084	--	--	--	No, excluded (Max < or = Table 6 SCS)
Trichlorofluoromethane	79	126	--	0.08	0.08	µg/g	4	--	--	--	No, excluded (Max < or = Table 6 SCS)
Uranium	68	109	2.6	1	2.6	µg/g	23	--	--	--	No, excluded (Max < or = Table 6 SCS)
Vinyl Chloride	79	125	--	0.02	0.02	µg/g	0.02	--	--	--	No, excluded (Max < or = Table 6 SCS)
Zirconium	23	27	19	--	19	µg/g	--	230	--	--	No, excluded (Max < or = Background value)

Notes:

[a] The representative maximum concentration (the maximum concentration of similar analytes or total concentration of multiple isomers) is used for comparison.
[b] Column lists the greater of the maximum detected concentration and the maximum nondetect concentration.
[c] Ontario Regulation 153/04, Table 6: Generic Site Condition Standards for Shallow Soils in a Potable Ground Water Condition for residential/parkland/institutional use and Coarse Textured Soils (MECP 2011).
[d] For aluminun, calcium, chloride, iron, magnesium, manganese, phosphorus, potasium, sodium, strontium, and titanium the Ontario Typical Ranges for an urban scenario are applied (MECP 2011). OTR values were adjusted to match the MECP derivation of the Table 1 Standards as presented on the "Background Calculations" tab of the MGRA (2016) and rounded to two significant figures per the rules applied in the MGRA. The value for zirconium is the average value reported by USGS.
U.S. Geological Survey. 1984. Element Concentrations in Soils and Other Surficial Materials of the Conterminous United States.

[e] For tin, a range has been shown represented by the CCME agricultural value of 5 µg/g (CCME 2020) on the low end; the high end value of 9.2 µg/g is the 98th percentile value of tin based on a soil survey conducted in agricultural soils in Southern Ontario by the Ontario Ministry of Agriculture, Food and Rural Affairs (OMFRA). These values represent the reasonable range of background tin concentrations that could be encountered in Ontario soils. The British Columbia Ministry of the Environment has derived a risk-based value for tin protective of human health of 25,000 µg/g and appears to have adopted the CCME value of 5 µg/g for the protection of ecological health. A search of soil screening values for ecological health on the Risk Assessment Information System (RAIS) website indicates that values between 7.62 µg/g and 2,000 µg/g are generally protective of ecological receptors (7.62 µg/g protective of mammals [masked shrew]; 50 µg/g protective of plants; 2,000 µg/g protective of soil microbes; 19 µg/g representing Dutch Background). Therefore, the CCME and background values are considered appropriate to use in the absence of MECP screening values for the selection of COCs. All tin concentrations measured onsite, apart from the maximum concentration are within the 5 to 9.2 µg/g range considered to be representative of "background". The maximum concentration of 9.6 µg/g is within the same order-of-magnitude as the "background" concentration range and could be within range if 20% analytical variability (a typical assumption) is considered. As such, tin was not retained as a COC for the Site.
Ontario Ministry of Agriculture, Food and Rural Affairs (OMFRA). 2005. Crop Advances: Field Project Reports, Volume 1. Field Crops Team, Crop Technology Branch, OMFRA.
British Columbia Ministry of the Environment. 1996. B.C. Reg. 375/96 - Contaminated Sites Regulation. Schedule 3.1, Parts 2 and 3
[f] Parameter is not applicable to human health.

Bold parameters are identified as COCs.

-- = no value or not applicable
< = less than
> = greater than
µg/g = microgram per gram
COC = contaminant of concern
F = fraction
Max = maximum concentration
OTR = Ontario Typical Range
MECP = Ontario Ministry of the Environment, Conservation and Parks
mS/cm = milliSiemen per centimetre
NA = not available
No. = number
PCB = polychlorinated biphenyls
PHC = petroleum hydrocarbons
SCS = Site Condition Standard
MGRA = modified generic risk assessment model

Table F1-2. Summary of COC Screening in Groundwater
Risk Assessment, 200 Beverley Street, Guelph, Ontario

Tungsten	1	1	--	0.1	0.1	µg/L	--	NA	--	--	No, excluded (no standard available; all results nondetect)
Uranium	70	91	17	--	17	µg/L	20	--	--	--	No, excluded (Max < or = Table 6 SCS)
Vanadium	70	99	1.66	5	5	µg/L	6.2	--	--	--	No, excluded (Max < or = Table 6 SCS)
Xylenes, Total	94	371	38.6	5	38.6	µg/L	72	--	--	--	No, excluded (Max < or = Table 6 SCS)
Zirconium	1	1	--	0.3	0.3	µg/L	--	NA	--	--	No, excluded (no standard available; all results nondetect)

[a] The representative maximum concentration (the maximum concentration of similar analytes or total concentration of multiple isomers) is used for comparison.
[b] Column lists the greater of the maximum detected concentration or the maximum nondetect concentration.
[c] Ontario Regulation 153/04, Table 6: Generic Site Condition Standards for Shallow Soils in a Potable Ground Water Condition for residential/parkland/institutional use and Coarse Textured Soils (MECP 2011).
[d] For nitrate, nitrite, sulfate, aluminum, magnesium, strontium, and titatnium, the Provincial Groundwater Monitoring Information System (PGMIS) is applied (MECP 2011).
[e] Value in brackets represents the theoretical maximum concentration of vinyl chloride. Refer to Table 4-7.
Notes:
Bold parameters are identified as COCs
-- = no value or not applicable
< = less than
> = greater than
µg/L = microgram(s) per litre
COC = contaminant of concern
F = fraction
INO = inorganic
MECP = Ontario Ministry of the Environment, Conservation and Parks
No. = number
PHC = petroleum hydrocarbon
SCS = Site Condition Standard

SCS = site condition standard
S-IA = Soil-to-Indoor Air
Torr = Torricelli

Appendix F2
Volatility Screening Tables

APPENDIX F2

Volatility Assessment

Approach

The potential fate and transport of a chemical is characterized, in part, by its physical and chemical properties. The vapour pressure of a chemical can indicate the likelihood that it will volatilize from its pure compound state; chemicals with high vapour pressures are expected to readily volatilize. The Henry's Law Constant (H) for a chemical indicates the theoretical amount of a chemical that will volatilize from the dissolved water phase to the vapour phase. The Ontario Ministry of the Environment, Conservation and Parks' (MECP's) definition of volatile includes chemicals with an H greater than 1×10^{-5} atmospheres per cubic metre per mol (atm-m^3/mol) or a vapour pressure greater than 0.05 Torricelli (Torr) (equivalent to 0.05 millimetres of mercury [mm Hg]) (MECP, 2019). Jacobs applied this definition to determine which chemicals were considered volatile for the purposes of risk assessment (RA), and to identify those that may require further analysis for the potential for risk and hazard from the inhalation of indoor or outdoor air, as applicable.

The MECP (2019) has provided a two-step screening process to determine if a chemical is of potential concern for vapour intrusion:

- **Step 1:** A chemical is considered to be sufficiently volatile and should be assessed as part of Step 2 if the chemical has either an H greater than 1×10^{-5} atm-m^3/mol), **or** a vapour pressure greater than 1.0 mm Hg (equivalent to 1.0 Torr)
- **Step 2:** If the maximum theoretical indoor air concentration of a chemical (based on conservative assumptions [C_{air}]) exceeds the applicable health based indoor air criteria (HBIAC) or odour thresholds (if available), then the chemical should be retained for vapour intrusion assessment in the RA.

Jacobs has added additional considerations to the Step 2 screening process, to incorporate the MECP (2016) soil-to-indoor air (S-IA), soil-to-indoor air odour (S-IA Odour), groundwater-to-indoor air (GW2), and groundwater-to-indoor air odour (GW2 Odour) component values (MECP, 2011). Therefore, chemicals retained for vapour intrusion assessment in the RA must meet **all** of the following criteria:

- The chemical is considered sufficiently volatile (per Step 1)
- The maximum theoretical indoor air concentration is greater than the associated HBIAC (or odour threshold)
- The associated soil or groundwater concentration is greater than the S-IA or S-IA Odour component (for soil) or the GW2 or GW Odour component (for groundwater)

In cases where the generic site condition standards may not be protective of the vapour pathway (that is, where the water table is less than 3 metres below ground surface), the Table 6 or Table 7 Standards (as applicable) were used in the screening process for groundwater. Under this scenario, chemicals were retained for vapour intrusion assessment if the maximum groundwater concentration was greater than the applied Table 6 or Table 7 Standard[1].

Table F2-1 applies the volatility definitions under Step 1 for the Site contaminants of concern (COCs) to determine which are considered volatile and require further assessment. Note, chemical properties provided in the Rationale Document (MECP, 2011) were used to complete this comparison (as noted in Table F2-1), unless otherwise indicated.

[1] The theoretical indoor air concentration does not also have to exceed the HBIAC (or odour threshold) for the chemical to be retained.

Jacobs has applied the MECP (2019) volatility guidance per Step 1 in all cases, apart from the following chemicals which were classified as nonvolatile for the purposes of the RA:

PHC F3 and F4 - The exclusion of the heavier PHC fractions as volatile is supported by guidance from other jurisdictions and agencies. The Canadian Council of Ministers of the Environment (CCME) (2008) considers PHC fraction (F)1 and F2 as volatile, and PHC F3 and F4 as nonvolatile. CCME indicates the heavier PHCs (that is, those in the C>16 range) are insufficiently volatile to pose an inhalation risk. PHC F3 is described as sparingly soluble in water and having very low volatility, and based on physical and chemical properties, PHCs of C>34 (that is, PHC F4) cannot dissolve in water or volatilize significantly.

Table F2-1 identifies the volatility designation for each RA Property COC and which COCs were retained for review under Step 2.

Table F2-2 applies the screening process described under Step 2 for the COCs retained under Step 1, and identifies the subset which will be carried forward as COCs for the vapour intrusion pathway. Jacobs also carried forward this subset of COCs for the outdoor air inhalation pathway.

Grey shading indicates the screening value that is exceeded by one or more of the estimated Indoor Air EPCs, the maximum soil concentration, or maximum groundwater concentration.

a. Obtained from Tables F1-1 and F1-2 (Appendix F1) for soil and groundwater, respectively.

b. The Henry's Law constants were corrected for an average vadose zone temperature of 15°C (EPA, 2001), with the exception of Total PCBs, which uses the Henry's Law constant at 25°C .

c. Represents the K_{oc} value multiplied by a factor of two.

d. Soil gas concentration at the soil source determined from the C_{soil} using phase relationships and partitioning from EPA (2004) as follows, $C_{sg} = C_{soil} * \rho_{db} * H * CF/(k_d * \rho_{db} + \epsilon_m + H * \epsilon_v)$, where the Henry's Law Constant is $H=H_L/(T*R)$, CF is a conversion factor of 10^6 mL/m^3, T is the vadose zone temperature in Kelvin, and the universal gas constant R is 8.206E-05 atm-m^3/ mol K, $k_d = K_{oc}*f_{oc}$.
The following vadose zone soil properties were applied:

	Coarse	
Total Porosity, ϵ_T (%)	36.0	Default total porosity for a Coarse soil texture, as implemented in MECP MGRA (2016).
Moisture-filled Porosity, ϵ_m	0.12	Default moisture-filled porosity for a Coarse soil texture, as implemented in MECP MGRA (2016).
Vapour-filled Porosity, ϵ_v	0.24	Calculated as $\epsilon_T/100-\epsilon_m$
ıry Bulk Soil Density, ρ_{db} (g/cm^3)	1.7	Default dry bulk density for a Coarse soil texture, as implemented in MECP MGRA (2016).
Soil Temperature (°C)	15	Default temperature for a Coarse soil texture, as implemented in MECP MGRA (2016).
ı of Organic Carbon Content, f_{oc}	0.005	Default fraction of organic carbon for a Coarse soil texture, as implemented in MECP MGRA (2016).

e. Soil gas concentration at the water table determined from C_{qw} using Henry's law as follows, $C_{sq} = C_{qw} * CF * H_L / (T*R)$, where CF is a conversion factor of 1,000 L/m^3, T is the vadose zone temperature in Kelvin, the universal gas constant R is 8.206E-05 atm m^3/ mol K, and the following vadose zone soil properties were applied:

Groundwater Temperature (°C)	15	Default temperature for a Coarse soil texture, as implemented in MECP MGRA (2016).

f. Default attenuation factor for a residential/parkland/institutional land use applied (MECP, 2011b).

g. The EPC in building is calculated from $C_{building} = C_{sg} , \alpha$.

h. Obtained from the MECP (2016) MGRA model.

i. Obtained from MECP (2011), GW2 component associated with the Table 6 SCS for a residential/parkland/institutional land use and a Coarse soil texture.

Notes:

-- = no value
µg/g = microgram(s) per gram
µg/L = microgram(s) per litre
µg/m^3 = microgram(s) per cubic metre
atm-m^3/mol = atmospheres per cubic metre per mol
EPA = United States Environmental Protection Agency
EPC = exposure point concentration
HBIAC = health based indoor air criteria
Max = maximum
MECP = Ministry of Environment, Conservation and Parks
mg/L = milligram(s) per litre
PHC = petroleum hydrocarbon
SCS = site condition standard
S-IA = soil-to-indoor air

Appendix G
Supporting Information and Calculations

Appendix G1
Sample Calculations

APPENDIX G1

Sample Calculations

The exposure parameters for the dermal uptake, ingestion, and inhalation route calculations presented in this appendix were obtained from Tables 4-1, 4-2, 4-9 to 4-12, 4-14, 4-20, 4-23, and 4-26 of the main report.

Dermal Uptake

Soil

The receptor's average uptake of contaminants of concern (COCs) through dermal contact with soil, or daily absorbed dose (DAD), is estimated using the following equation (based on MECP, 2011):

$$DAD = \frac{C*DAF*SAF*ESSA*CF*EF1*EF2*ED}{BW*AT} \quad (1)$$

where:

DAD = Daily absorbed dose via dermal contact (milligrams per kilograms per day [mg/kg-day])

C = Chemical concentration in soil (mg/kg)

SAF = Soil adherence factor (milligrams per square centimetre per day [mg/cm^2-day])

DAF = Dermal absorption factor (unitless)

ESSA = Exposed skin surface area (cm^2)

CF = Conversion factor (10^{-6} kg/mg)

EF1 = Exposure frequency (weeks/year)

EF2 = Exposure frequency (days/week)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging time (days)

This calculation of DAD via dermal contact assumes one soil contact event per day. Exposure assumptions related to the Construction Worker receptor are applied to demonstrate this calculation. The COC selected for demonstration is phenanthrene. As phenanthrene is noncarcinogenic, an averaging time representative of noncarcinogenic exposure is applied. As such, the exposure parameters are as follows:

C = 1000 mg/kg

SAF = 0.2 mg/cm^2/day

DAF = 0.13

ESSA = 3,400 cm^2

CF = 1E-06 kg/mg

EF1 = 39 weeks/year

EF2 = 5 days/week

ED = 1.5 years

BW = 70.7 kg

AT = 1.5 years x 365 days/year = 547.5 days

Therefore:

$$DAD = \frac{1000*0.2*0.13*3400*0.000001*39*5*1.5}{70.7*547.5}$$

$$DAD = 7.E-04\frac{mg}{kg}-day$$

Risk from noncarcinogenic exposures are estimated as:

$$HQ = \frac{DAD}{RfD} \quad (2)$$

Where:

HQ = hazard quotient (unitless)

DAD = daily absorbed dose (mg/kg/day)

RfD = Reference Dose (mg/kg/day)

The inputs to calculate noncarcinogenic risk associated with phenanthrene for Construction Worker dermal contact in soil are as follows:

DAD = 7.E-04 mg/kg/day

RfD = 0.04 mg/kg/day

Therefore:

$$HQ = \frac{7.E-04}{0.04}$$

$$HQ = 2E-02$$

Groundwater

A receptor's average uptake of COCs through dermal contact with groundwater is estimated using the following equation (based on EPA, 2004):

$$DAD = \frac{DA_{event}*FE*ESSA*EF1*EF2*ED}{BW*AT} \quad (3)$$

Where:

DAD = Daily absorbed/administered dose (mg/kg-day)

DA_{event} = Absorbed dose per event (mg/cm^2-event)

FE = Frequency of events (event/day)

ESSA = Exposed skin surface area (cm^2)

*EF*1 = Exposure frequency (days/week)

*EF*2 = Exposure frequency (weeks/year)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging time (days)

The dose absorbed per unit area per event (DA_{event}) equation for calculating dermal exposure to water is estimated using the following equations (based on EPA, 2004):

For organic COCs:

$$If\ t_{event} \leq \mathrm{t}^{*}, \text{then}\ DA_{event} = 2 \times \mathrm{FA} \times Kp \times \mathrm{C} \times \sqrt{\frac{6 \times \tau_{event} \times t_{event}}{\pi}}$$

$$If\ t_{event} > \mathrm{t}^{*}, \text{then}\ DA_{event} = \mathrm{FA} \times Kp \times \mathrm{C} \times \left[\frac{t_{event}}{1+B} + 2 \times \tau_{event} \times \left(\frac{1+3\times B+3\times B^{2}}{(1+B^{2})}\right)\right] \quad (4)$$

For inorganic COCs:

$$DA_{event} = Kp \times \mathrm{C} \times t_{event} \quad (5)$$

where:

C = Chemical concentration in groundwater (mg/cm^3)

FA = Fraction absorbed water (dimensionless)

K_p = Dermal permeability coefficient of compound in water (cm/hr)

t_{event} = Event duration (hr/event)

τ_{event} = Lag time per event (hr/event)

t* = Time to reach steady state (hr) = 2.4 x τ_{event}

B = Dimensionless ratio of the permeability coefficient of a compound through the stratum corneum relative to its permeability coefficient across the viable epidermis (dimensionless)

Exposure assumptions related to the Construction Worker receptor are applied to demonstrate this calculation. The COC selected for demonstration is benzo(a)pyrene. As benzo(a)pyrene is carcinogenic, an averaging time representative of carcinogenic exposure is applied. The exposure parameters are as follows:

C = 0.0000028 mg/cm^3

FA = 1.0

K_p = 7.13E-01 cm/hr

t_{event} = 0.083 hr/event

t* = 12.1 hr

τ_{event} = 2.77 hr/event

DA_{event} = 2.65E-06 mg/cm^2-event

FE = 1 event/day

ESSA = 3400 cm^2

EF1 = 5 days/week

EF2 = 39 weeks/year

ED = 1.5 years

BW = 70.7 kg

AT = 56 years x 365 days/year = 20,440 days

For inorganic COCs, the variables to caclulate DA_{event} are provided in equation (5).

For organic COCs, the variables to calculate DA_{event} associated with benzo(a)pyrene for Construction Workers dermal contact with groundwater depend on if $t_{event} \leq$ or $> t^*$

If the parameter is organic and $t_{event} \leq t^*$, the first part of equation (4) is used to calculate DA_{event} and the following statements are true:

If $B \leq 0.6$, then t^* is calculated as:

$$t^* = 2.4 \times \tau_{event} \quad (6)$$

If $B > 0.6$, then t^* is calculated as:

$$t^* = 6\tau_{event}\ (b - \sqrt{b^2 - c^2}) \quad (7)$$

Where b and c are calculated as:

$$b = \frac{2(1+B)^2}{\pi} - c \quad (8)$$

$$c = \frac{1+3B+3B^2}{3(1+B)} \quad (9)$$

τ_{event} is calculated as:

$$\tau_{event} = \frac{isc^2}{6\times\{[10^{(-2.805063-0.0056118\times MW)}]\times isc\}} \quad (10)$$

Where:

isc = thickness of the skin stratum (cm)

MW = molecular weight (g/mol)

If the parameter is organic and $t_{event} \geq t^*$, equation (5) is used to calculate DA_{event} and the following statements are true:

t^* is calculated per equations (6) and (7).

τ_{event} is calculated per equation (10).

B is calculated as:

$$B = \frac{K_p\sqrt{MW}}{2.6} \quad (11)$$

The inputs to calculate τ_{event} and t^* associated with benzo(a)pyrene for Construction Workers dermal contact with groundwater are as follows:

isc =0.001 cm

MW = 252.32 g/mol

Therefore, τ_{event} is calculated as:

$$\tau_{event} = \frac{0.001^{\,2}}{6 \times \{[10^{(-2.805063-0.0056118\times 252.32)}] \times 0.001\}}$$

$$\tau_{event} = 2.77\ hr/event$$

Therefore, B is calculated as:

$$B = \frac{7.13\mathrm{E}-01\sqrt{252.32}}{2.6}$$

$$B = 4.35$$

Therefore, t^* is calculated as:

$$t^* = 6 * 2.77\ (1.38E+01 - \sqrt{1.38E+01^2 - 4.42^2})t^* = 1.21E+01\ hr/event$$

Where b and c are:

$$b = \frac{2(1+4.35)^2}{\pi} - 4.42$$

$$b = 1.38E+01$$

$$c = \frac{1 + 3 * 4.35 + 3(4.35)^2}{3(1+4.35)}$$

$$c = 4.42$$

Benzo(a)pyrene is an organic parameter; $t_{event} \leq t^*$; therefore, using equation (4), DA_{event} is calculated as follows:

$$DA_{event} = 2 * 1.0 * 7.13E-01 * 0.0000028 * \sqrt{\frac{6 * 0.083 * 2.77}{\pi}}$$

$$DA_{event} = 2.65E-06$$

Therefore:

$$DAD = \frac{2.65E-06*1*3400*5*39*1.5}{70.7*20440} \quad (12)$$

$$DAD = 2.E-06\frac{mg}{kg}-day$$

Risk from carcinogenic exposures are estimated as:

$$ILCR = DAD * SF \quad (13)$$

Where:

ILCR = incremental lifetime cancer risk (unitless)

DAD = daily absorbed dose (mg/kg/day)

SF = slope factor [mg/kg/day]$^{-1}$)

The inputs to calculate carcinogenic risk associated with benzo(a)pyrene for Construction Workers dermal contact with groundwater are as follows:

DAD = 2.E-06 mg/kg/day

SF = 1.0 $(mg/kg/day)^{-1}$

Therefore:

$$ILCR = 2.E-06 * 1.0$$

$$ILCR = 2.\mathrm{E}-06$$

Ingestion

Soil

The receptor's average uptake of COCs through incidental ingestion of soil is estimated using the following equation (based on EPA, 1989):

$$DAD = \frac{C*IRs*GIAF*CF*EF1*EF2*ED}{BW*AT} \quad (14)$$

Where:

DAD = Daily absorbed dose via incidental ingestion (mg/kg-day)

C = Chemical concentration in soil (mg/kg)

IR_S = Quantity of soil ingested daily (mg/day)

GIAF = Gastrointestinal absorption factor (unitless)

CF = Conversion factor (10^{-6} kg/mg)

EF1 = Exposure frequency (weeks/year)

EF2 = Exposure frequency (days/week)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging time (days)

Exposure assumptions related to the Utility Worker receptor are applied to demonstrate this calculation. The COC selected for demonstration is arsenic. As arsenic is carcinogenic, an averaging time representative of carcinogenic exposure is applied. The exposure parameters are as follows:

C = 27 mg/kg

IR_S = 100 mg/day

GIAF = 0.5

CF = 1E-06 kg/mg

EF1 = 2 weeks/year

EF2 = 5 days/week

ED = 56 years

BW = 70.7 kg

AT = 56 years x 365 days/year = 20,440 days

Therefore:

$$DAD = \frac{27*100*0.5*0.000001*2*5*56}{70.7*20440}$$

$$DAD = 5.E-07 \frac{mg}{kg} - day$$

Risk from carcinogenic exposures are estimated as:

$$ILCR = DAD * SF \quad (12)$$

Where:

ILCR = incremental lifetime cancer risk (unitless)

DAD = daily absorbed dose (mg/kg/day)

SF = slope factor [mg/kg/day]$^{-1}$)

The inputs to calculate carcinogenic risk associated with arsenic for Utility Workers incidental ingestion of soil are as follows:

DAD = 5.E-07 mg/kg/day

SF = 9.5 (mg/kg/day)$^{-1}$

Therefore:

$$ILCR = 5.E-07 * 9.5$$

$$ILCR = 5.\mathrm{E}-06$$

Groundwater

The receptor's average uptake of COCs through incidental ingestion of groundwater is estimated using the following equation (MECP, 2011; USEPA, 1989):

$$DAD = \frac{C*IR_W*GIAF*FE*CF*EF1*EF2*ED}{BW*AT} \quad (13)$$

where:

DAD = Daily absorbed/administered dose (mg/kg-days)

C = Chemical concentration in groundwater (micrograms per litre [µg/L])

IR_W = Quantity of groundwater ingested daily (L/event)

GIAF = Gastrointestinal absorption factor (unitless)

FE = Frequency of events (events/day)

CF = Conversion factor (0.001 mg/µg)

EF1 = Exposure frequency (weeks/year)

EF2 = Exposure frequency (days/week)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging time (days)

Exposure assumptions related to the Construction Worker receptor are applied to demonstrate this calculation. The COC selected for demonstration is benzo(a)pyrene. As benzo(a)pyrene is carcinogenic, an averaging time representative of carcinogenic exposure is applied. The exposure parameters are as follows:

C = 2.8 µg/L

IR_W = 0.05 L/event

GIAF = 1.00

FE = 1 event/day

CF = 0.001 mg/µg

*EF*1 = 39 weeks/year

*EF*2 = 5 days/week

ED = 1.5 years

BW = 70.7 kg

AT = 1.5 years x 365 days/year = 547.5 days

Therefore:

$$DAD = \frac{2.8*0.05*1*1*0.001*39*5*1.5}{70.7*547.5}$$

$$DAD = 1.E-06 \frac{mg}{kg}/day$$

Risk from noncarcinogenic exposures are estimated as:

$$HQ = \frac{DAD}{RfD} \quad (14)$$

Where:

HQ = hazard quotient (unitless)

DAD = daily absorbed dose (mg/kg/day)

RfD = Reference Dose (mg/kg/day)

The inputs to calculate noncarcinogenic risk associated with benzo(a)pyrene for Construction Worker dermal contact in soil are as follows:

DAD = 1.E-06 mg/kg/day

RfD = 0.005 mg/kg/day

Therefore:

$$HQ = \frac{1.E-06}{0.005}$$

$$HQ = 2E-04$$

Inhalation

Particulates

The receptor's average uptake of COCs through the inhalation of soil particulate is estimated using the following equation (based on MECP, 2011; Health Canada, 2010):

$$DAD = \frac{C*PM_{10}*CF*IR_A*FPM_{inh}*EF1*EF2*EF3*ED}{BW*AT} \quad (15)$$

Where:

DAD = Daily administered dose (mg/kg-day)

C = Chemical concentration in soil (mg/kg)

PM_{10} = Particulate concentration in air (micrograms of soil per cubic metre [µg-soil/m^3])

CF = Conversion factor, 1 kg/10^9 µg

IR_A = Inhalation rate (m^3/hour)

FPM_{inh} = Fraction of PM10 (unitless); MECP default value of 0.6 is applied herein

*EF*1 = Exposure frequency (days/week)

*EF*2 = Exposure frequency (weeks/year)

*EF*3 = Exposure frequency (hours/day)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging time (days)

Exposure assumptions related to the Construction Worker receptor are applied to demonstrate this calculation. The COC selected for demonstration is phenanthrene. As phenanthrene is noncarcinogenic, an averaging time representative of noncarcinogenic exposure is applied. The exposure parameters are as follows:

C = 1000 mg/kg

PM_{10} = 100 µg-soil/m^3

CF = 1 kg/10^9 µg

IR_A = 1.5 m^3/hour

FPM_{inh} = 0.6

*EF*1 = 5 days/week

*EF*2 = 39 weeks/year

*EF*3 = 9.8 hours/day

ED = 1.5 years

BW = 70.7 kg

AT = 1.5 x 365 = 547.5 days

Therefore:

$$DAD = \frac{1000*100*1E-09*1.5*0.6*5*39*9.8*1.5}{70.7*547.5}$$

$$DAD = 7.E-06\ mg/kg\ -day$$

Risk from noncarcinogenic exposures are estimated as:

$$HQ = \frac{DAD}{RfD_i} \quad (16)$$

Where:

HQ = hazard quotient (unitless)

DAD = daily absorbed dose (mg/kg/day)

RfD$_i$ = Inhalation Reference Dose (mg/kg/day)

Toxicity values that correspond to exposure doses (as opposed to concentrations) are required for evaluation of risk from particulates. Therefore, reference concentrations (RfCs) and unit risk factors (URFs) require conversion to RfD$_i$ and SF$_i$ values. The conversion factor for adults involves the EPA defaults of a daily inhalation rate of 20 cubic metres per day (m^3/day) and a body weight of 70 kg (University of Tennessee, 2013). The conversion is as follows:

$$RfD_i(mg/kg/day) = \frac{RfC(mg/m^3)*20(m^3/day)}{70(kg)} \quad (17)$$

and

$$SF_i([mg/kg/day]^{-1}) = \frac{URF([mg/m^3]^{-1})*10^3(\mu g/mg)*70(kg)}{20(m^3/day)} \quad (18)$$

The conversion of the noncarcinogenic RfC for phenanthrene of 5.0E-02 mg/m^3, to an RfD$_i$ for evaluation of particulates, is conducted as follows:

$$RfD_i = \frac{5.0E-02*20}{70} \quad (19)$$

$$RfD_i = 1.43E-02$$

Therefore:

$$HQ = \frac{7.E-06}{1.43E-02}$$

$$HQ = 5.E-04$$

Volatiles

The receptor's average uptake of COCs through the inhalation of volatiles in air is estimated using the following equation (based on EPA, 2009):

$$EC = \frac{(C_{air}*EF1*EF2*EF3*ED)}{AT} \quad (20)$$

Where:

EC = Exposure concentration (mg/m^3)

C_{air} = Volatile contaminant concentration in indoor or outdoor air (mg/m^3); these concentrations are obtained through modelling, as described in Appendices G3 and G4

EF1 = Exposure frequency (days/week)

EF2 = Exposure frequency to either indoor or outdoor air (weeks/year)

EF3 = Exposure frequency to either indoor or outdoor air (hours/day)

ED = Exposure duration (years)

AT = Averaging time (hours)

Exposure assumptions related to the Construction Worker receptor for outdoor air exposure to volatiles originating in the subsurface are applied to demonstrate this calculation. The COC selected for demonstration is benzene for a Construction Worker within a trench. As benzene is carcinogenic, an averaging time representative of carcinogenic exposure is applied. The exposure parameters are as follows:

C_{air} = 1.23E-04 mg/m^3

EF1 = 5 days/week

EF2 = 39 weeks/year

EF3 = 9.8 hours/day

ED = 1.5 years

AT = 56 x 365 x 24 = 490,560 hours

Therefore:

$$EC = \frac{1.23E{-}04{*}5{*}39{*}9.8{*}1.5}{490{,}560}$$

$$EC = 7.E-07\ mg/m^3$$

Risk from carcinogenic exposures are estimated as:

$$ILCR = EC * UR \quad (21)$$

Where:

ILCR = incremental lifetime cancer risk (unitless)

EC = daily absorbed dose (mg/m^3)

UR = unit risk ([mg/m^3]$^{-1}$)

The inputs to calculate carcinogenic risk associated with inhalation of benzene for Construction Workers in a trench are as follows:

EC = 7.E-07 mg/m^3

UR = 2.2E-03 (mg/m^3)$^{-1}$

Therefore:

$$ILCR = 7.E-07 * 2.2E-03$$

$$ILCR = 2.\mathrm{E}-9$$

Composite Receptor

For the composite receptor, exposure is expressed as the Lifetime Average Daily Dose (LADD) or Lifetime Average Exposure Concentration (LAEC). To calculate LADD or LAEC, the averaging time for each life stage is set equal to the lifetime exposure duration (that is, 76 years), and the individual contributions of each life stage are then summed. Thus, the composite receptor's LADD for any COC through either the ingestion of soil, dermal contact with soil, or the inhalation of dust pathway is estimated using the following equation:

$$LADD = DAD_{\text{inf}\,ant} + DAD_{toddler} + DAD_{child} + DAD_{teem} + DAD_{adult} \qquad (22)$$

Where:

LADD = LADD of the composite receptor for the specified pathway (mg/kg-days)

DAD_{infant} = DAD of infant for the specified pathway with averaging time set to 27,740 days (that is, 76 years) (mg/kg-days)

$DAD_{toddler}$ = DAD of toddler for the specified pathway with averaging time set to 27,740 days (mg/kg-days)

DAD_{child} = DAD of child for the specified pathway with averaging time set to 27,740 days (mg/kg-days)

DAD_{teen} = DAD of teen for the specified pathway with averaging time set to 27,740 days (mg/kg-days)

$DAD_{adul\ t}$ = DAD of adult for the specified pathway with averaging time set to 27,740 days (mg/kg-days)

For example, for the evaluation of the composite receptor's LADD from dermal exposure to soil:

$$DAD_{\text{inf}\,ant} = \frac{C * DAF * SAF_{\text{inf}\,ant} * ESSA_{\text{inf}\,ant} * CF * EF1 * EF2 * ED_{\text{inf}\,ant}}{BW_{\text{inf}\,ant} * 27740} \qquad (23)$$

$$DAD_{toddler} = \frac{C * DAF * SAF_{toddler} * ESSA_{toddler} * CF * EF1 * EF2 * ED_{toddler}}{BW_{toddler} * 27740} \qquad (24)$$

$$DAD_{child} = \frac{C * DAF * SAF_{child} * ESSA_{child} * CF * EF1 * EF2 * ED_{child}}{BW_{child} * 27740} \qquad (25)$$

$$DAD_{teen} = \frac{C * DAF * SAF_{teen} * ESSA_{teen} * CF * EF1 * EF2 * ED_{teen}}{BW_{teen} * 27740} \qquad (26)$$

$$DAD_{adult} = \frac{C * DAF * SAF_{adult} * ESSA_{adult} * CF * EF1 * EF2 * ED_{adult}}{BW_{adult} * 27740} \qquad (27)$$

And subsequently:

$$LADD = DAD_{\text{inf}\,ant} + DAD_{toddler} + DAD_{child} + DAD_{teem} + DAD_{adult}$$

The composite receptor's LAEC for the inhalation of volatile COCs in indoor or outdoor air is estimated in a similar manner, using the following equation:

$$LAEC = EC_{\text{inf ant}} + EC_{toddler} + EC_{child} + EC_{teem} + EC_{adult} \quad (28)$$

Where:

LAEC = LAEC of the composite receptor for the specified pathway (mg/m^3)

EC_{infant} = EC of infant for the specified pathway with averaging time set to 27,740 days (mg/m^3)

$EC_{toddler}$ = EC of toddler for the specified pathway with averaging time set to 27,740 days (mg/m^3)

EC_{child} = EC of child for the specified pathway with averaging time set to 27,740 days (mg/m^3)

EC_{teen} = EC of teen for the specified pathway with averaging time set to 27,740 days (mg/m^3)

EC_{adult} = EC of adult for the specified pathway with averaging time set to 27,740 days (mg/m^3)

Pregnant Female Receptor

The MECP Rationale Document (2011) advises that:

> *"Pro-rating for exposure frequency is not applied in the derivation of human health based component values based on developmental effects because the relevant duration of exposure is assumed to be short-term. This is because a single exposure to a chemical with developmental toxicity, rather than repeated or extended exposure, may be sufficient to elicit an adverse developmental effect."*

As such, Pregnant Female receptors have been assessed, and are assumed to be onsite (within buildings or outdoors) for 24 hours per day, 7 days per week, 52 weeks per year, for 56 years. These calculations only apply to noncarcinogenic COCs with developmental effects (listed in Section 4.3.2.1 of the main text) for inhalation pathways (refer to Section 4.2.1 of the main text).

The inhalation of dust pathway (refer to Equation 13) has been selected to demonstrate the calculations for Pregnant Female receptors. Exposure assumptions related to the Pregnant Female Resident receptor are applied. The COC selected for demonstration is benzo(a)pyrene, which has been identified as a COC with noncarcinogenic developmental effects. The exposure parameters are as follows:

C = 150 mg/kg

PM_{10} = 0.76 µg-soil/m^3

CF = 1 kg/10^9 µg

IR_A = 0.692 m^3/hour

FPM_{inh} = 0.6

EF1 = 7 days/week

EF2 = 52 weeks/year

EF3 = 24 hours/day

ED = 56 years

BW = 63.1 kg

AT = 56 years x 365 days/year = 20,440 days

Therefore:

$$DAD = \frac{150*0.76*1E-09*0.692*0.6*7*52*24*56}{63.1*20440}$$

$$DAD = 2.E-8\ mg/kg-day$$

Risk from noncarcinogenic exposures are estimated as:

$$HQ = \frac{DAD}{RfD_i} \quad (29)$$

Where:

HQ = hazard quotient (unitless)

DAD = daily absorbed dose (mg/kg/day)

RfD_i = Inhalation Reference Dose (mg/kg/day)

Refer to Equation 13 for the procedure for converting the RfC to an RfD_i. The RfD_i for benzo(a)pyrene is 5.7E-07 mg/kg/day, calculated from an RfC of 2.E-06 mg/m^3.

Therefore:

$$HQ = \frac{2.E-8}{5.7E-07}$$

$$HQ = 3.E-02\ mg/kg-day$$

Appendix G2
Soil- and Groundwater-to-Indoor-Air Modelling

APPENDIX G2

Soil and Groundwater to Indoor Air Modelling

Approach

In September 1998, the U.S. Environmental Protection Agency (EPA) developed a series of models to estimate indoor air concentrations and associated health risks from subsurface vapour intrusion into buildings. These models were based on the analytical solutions of Johnson and Ettinger (J&E) (J&E 1991) for contaminant partitioning and subsurface vapour transport into buildings.

This appendix presents the J&E Model input parameters used for soil-to-indoor-air and groundwater-to-indoor-air modelling at the Risk Assessment (RA) Property. Specifically, the J&E Model Version 3.1 (EPA 2004) was used to develop attenuation factors for a generic residential building and generic commercial building. The building type included in the modelling was intended to conservatively represent potential future conditions at the RA Property. Once the attenuation factors were determined, they were applied to the estimated soil gas concentrations to estimate indoor air concentrations. Volatile partitioning relationships, discussed herein, were applied to soil and groundwater data to produce estimated soil gas concentrations at the source.

Depth to Groundwater

The presence of contaminated groundwater near a building foundation may preclude the use of the J&E Model for modelling vapour intrusion from groundwater. If the groundwater elevation is within 1.0 metres (m) of a building foundation, the J&E model is not considered applicable, and the Ontario Ministry of the Environment, Conservation and Parks (MECP) default attenuation factors of 0.02 for a residential building and 0.004 for a commercial building are used. Because groundwater elevations can fluctuate from spring to winter, the minimum depth to groundwater was used to account for seasonal variations in the water table, to determine whether the MECP default attenuation factor or the J&E Model would be used to estimate the indoor air exposure point concentrations from groundwater. Table G2-1 summarizes the minimum, average, and maximum depths to groundwater using data from 27 water level events from 2010 to 2020 (Jacobs 2020 – in progress). Overall, the minimum, maximum, and average groundwater depths are 0.93, 4.97, and 2.70 metres below ground surface (mbgs), respectively. The minimum groundwater depth selected for this assessment is 0.93 mbgs, based on a measurement collected in December 2011.

Table G2-2 summarizes the overall groundwater depths relative to the foundation depths of the generic residential and generic commercial building scenarios. Considering the minimum depth to groundwater at the RA Property, a separation distance of less than 1.0 m is present for both scenarios. As such, J&E-modelled attenuation factors were applied for the estimation of indoor air concentrations for the soil-to-indoor air pathway and MECP default attenuation factors were applied for the estimation of indoor air concentrations for the groundwater-to-indoor air pathway for the generic residential and commercial building scenarios.

Johnson and Ettinger Model Input Parameters

The J&E Model is a one-dimensional analytical solution for convective and diffusive vapour transport into indoor spaces, and provides an estimated attenuation coefficient that relates the vapour concentration in the indoor air space to the vapour concentration at the source of contamination. Inputs to the J&E Model include chemical parameters of the volatile compounds, saturated and unsaturated zone soil properties, and structural properties of the building. Default model input parameters are available from the MECP Rationale Document (MECP 2011). Site-specific model inputs are based on information gathered during

previous investigations (for example, depth to groundwater and structural properties of existing buildings, if applicable). Table G2-3 lists the J&E Model input parameters. The following is a brief discussion of select input parameters used to develop attenuation factors for the RA Property:

- Depth of Contamination (Source—Building Separation or L_T) – Depth of contamination represents separation between the contaminant and the structure. For all modelled building scenarios, this value is represented by the default value for the depth below grade to bottom of enclosed space floor, adjusted by 30 centimetres (cm) to account for a gravel crush layer that is required beneath the basement/foundation slab by the Ontario Building Code.
- Depth Below Grade to Water Table (L_{WT}) – Represented by the minimum depth to groundwater measured at the RA Property.
- Soil Type – The EPA (2004) version of the J&E model contains default soils characteristic information for the 12 Soil Conservation Survey soil texture classifications. Soil texture for the RA Property was identified as coarse-textured soil (fill). Because the maximum depth of fill is below the depth of a typical commercial slab-on-grade foundation, it is expected to remain beneath commercial buildings in the future. As such, the Soil Conservation Survey texture classification for sand was selected to best describe the site soil conditions. Strata A and C were based on the sand Soil Conservation Survey classification. Stratum B was applied to represent the 30-cm gravel crush layer required beneath the basement/foundation slab by Ontario Building Code.
- Fraction of Organic Carbon (f_{oc}) – Represented by MECP default (0.005).
- Enclosed Space Volume (Floor Length, Width, and Height) – The indoor air mixing volume is based on the length, width, and height of a building, assuming air in the structure is evenly distributed. The generic residential building dimensions were based on the MECP default values for a residential building, while the generic commercial building dimensions were based on the MECP default values for a commercial building.
- Average Vapour Flow Rate into Building – The MECP default vapour flow rate was applied. Table G2-3 provides the MECP default values for coarse-textured soil for a generic residential building and a generic commercial building.
- Soil Vapour Permeability – The MECP default soil vapour permeability was applied. Table G2-3 provides the MECP default values for coarse-textured soil for a generic residential building and generic commercial building.

To calculate the attenuation factors from impacted soil, the infinite source model function of the J&E Model was used. However, the infinite source model may not be representative of site conditions at the RA Property. Section 4 of the RA report discusses uncertainty associated with use of the infinite source model.

As the calculation of attenuation factors in the J&E Model is independent of soil and groundwater concentrations, chemical concentrations were entered into the J&E Model as 1 microgram per kilogram and 1 microgram per litre for soil and groundwater, respectively.

The DATAENTER and INTERCALCS spreadsheets from the J&E Model for soil are provided at the end of this appendix.

Calculation of Indoor Air Concentrations

Indoor air concentrations are estimated by applying the attenuation factors (developed, for this RA, using the J&E Model and MECP defaults) to estimated soil gas concentrations. Soil gas concentrations at the source are estimated by applying volatile partitioning relationships to soil and groundwater data, as demonstrated in Tables G2-4a, G2-4b, G2-5a, and G2-5b.

Tables G2-4a and G2-4b also present the equations used to calculate the soil gas concentrations from soil data for the generic commercial and generic residential building scenarios, respectively. Tables G2-5a and G2-5b present the equations used to calculate the soil gas concentrations from groundwater data for the generic commercial and generic residential building scenarios, respectively.

Table G2-3. J&E Model Inputs

Risk Assessment, 200 Beverley Street, Guelph, Ontario

Input	Generic Residential Building	Generic Commercial Building	Source/Reference
Average Soil/Groundwater Temperature, T_S (°C)	15	15	The default value applied in the Rationale Document (MECP 2011).
Depth below grade to bottom of enclosed space floor, L_F (cm)	158	11.25	The default value applied in the Rationale Document (MECP 2011).
Depth below grade to water table, L_{WT} (cm)	93	93	The minimum depth to groundwater at the RA Property.
Depth below grade to top of contamination, L_t (cm)	188	41.25	A separation distance of 30 cm for crushed gravel layer is applied between the slab and volatile soil impacts.
Depth below grade to bottom of contamination, L_b (cm)	0	0	A value of zero invokes the infinite or nondiminishing source model.
Thickness of soil stratum A, h_A (cm)	See L_F	See L_F	Stratum A must be at least as thick as the depth below grade to the bottom of the enclosed space floor. See L_F.
Thickness of soil stratum B, h_B (cm)	29.9	29.9	Default value applied in MGRA Model (MECP 2016).
Thickness of soil stratum C, h_C (cm)	Soil Model: $h_C = L_t - L_F - h_B$ Groundwater Model: $h_C = L_{WT} - L_F - h_B$	Soil Model: $h_C = L_t - L_F - h_B$ Groundwater Model: $h_C = L_{WT} - L_F - h_B$	Totals of h_A, h_B, and h_C must add up to L_t in soil model and L_{WT} in J&E groundwater model.
Enclosed Space Floor Thickness, L_{crack} (cm)	8	11.25	The default value applied in the Rationale Document (MECP 2011).
Soil Building Pressure Differential, ΔP (g/cm-s^2)	40	20	The default value applied in the Rationale Document (MECP 2011).
Enclosed space floor length, L_B (cm)	1225	2000	The default value applied in the Rationale Document (MECP 2011).
Enclosed space floor width, W_B (cm)	1225	1500	The default value applied in the Rationale Document (MECP 2011).
Enclosed space height, H_B (cm)	366	300	The default value applied in the Rationale Document (MECP 2011).
Floor-wall seam crack width (cm)	0.1	0.1	The default value applied in the Rationale Document (MECP 2011).
Indoor Air Exchange Rate, ER (1/h)	0.3	1	The default value applied in the Rationale Document (MECP 2011).
Average Vapour Flow Rate into Building, Q_{soil} (L/min)	8.45	9.8	The default value applied in the Rationale Document (MECP 2011) for coarse-textured soil by building type.
Soil Vapour Permeability (cm^2)	1.63E-07	1.78E-07	The default value applied in the Rationale Document (MECP 2011) for coarse-textured soil by building type.
Stratum A and C SCS soil type	S	S	Sand – based on observations at the RA Property.

Table G2-3. J&E Model Inputs

Risk Assessment, 200 Beverley Street, Guelph, Ontario

Input	Generic Residential Building	Generic Commercial Building	Source/Reference
Total Porosity	0.375	0.375	The default value applied in the J&E Model (EPA 2004) for Sand.
Moisture-filled porosity	0.054	0.054	The default value applied in the J&E Model (EPA 2004) for sand.
Fraction of Organic Carbon	0.005	0.005	The default value applied in the J&E Model (EPA 2004) for sand.
Dry Bulk Density (g/cm^3)	1.66	1.66	The default value applied in the J&E Model (EPA 2004) for sand.
Stratum B SCS soil type	NA – Gravel Crush Layer	NA – Gravel Crush Layer	NA
Total Porosity	0.4	0.4	Default value for gravel crush applied in MGRA Model (MECP 2016).
Moisture-filled porosity	0.01	0.01	Default value for gravel crush applied in MGRA Model (MECP 2016).
Fraction of Organic Carbon	0	0	Default value for gravel crush applied in MGRA Model (MECP 2016).
Dry Bulk Density (g/cm^3)	1.6	1.6	Default value for gravel crush applied in MGRA Model (MECP 2016).

U.S. Environmental Protection Agency (EPA). 2004. *User's Guide for Evaluating Subsurface Vapor Intrusion into Buildings* . Washington, D.C.: Office of Emergency and Remedial Response. February 22.

a. The applied chemical properties were obtained from MECP (2011a). The Henry's Law constants were corrected for an average vadose zone temperature of 15°C.

b. Soil exposure point concentrations applied.

c. Soil gas concentration at the soil source determined from the C_{soil} using phase relationships and partitioning from EPA (2004) as follows, $C_{sg} = C_{soil} * \rho_{db} * H * CF/(k_d * \rho_{db} + \varepsilon_m + H * \varepsilon_v)$, where the Henry's Law Constant is $H=H_L/(T*R)$, CF is a conversion factor of 10^6 mL/m³, T is the vadose zone temperature in Kelvin, and the universal gas constant R is 8.206E-05 atm-m³/ mol K, $k_d = K_{oc}*f_{oc}$.
The following vadose zone soil properties were applied:

Total Porosity, ε_T (%)	37.5	Default total porosity for a sand soil type, as implemented in EPA (2004).
Moisture-filled Porosity, ε_m	0.054	Default moisture-filled porosity for a sand soil type, as implemented in EPA (2004).
Vapour-filled Porosity, ε_v	0.321	Calculated as $\varepsilon_T/100-\varepsilon_m$
Dry Bulk Soil Density, ρ_{db} (g/cm³)	1.66	Default dry bulk density for a sand soil type, as implemented in EPA (2004).
Soil and Groundwater Temperature (°C)	15	Default temperature, as indicated in MECP (2011a).
Fraction of Organic Carbon Content, f_{oc}	0.005	Default fraction of organic carbon, as implemented in MECP MGRA (2011b).

d. The calculation of the soil gas attenuation factor was conducted using the Microsoft Excel spreadsheet "SL-ADV-Feb04.xls" developed by USEPA (2004).

e. The EPC in the building is calculated from $C_{building} = C_{sg} * \alpha$.

b. Groundwater Estimated Maximum Concentrations applied.

c. Soil gas concentration at the water table determined from C_{gw} using Henry's law as follows, $C_{sg} = C_{gw} * CF * H_L / (T*R)$, where CF is a conversion factor of 1,000 L/m^3, T is the vadose zone temperature in Kelvin, the universal gas constant R is 8.206E-05 atm m^3/ mol K, and the following vadose zone soil properties were applied:

Soil/Groundwater Temperature (°C)	15	Default temperature, as indicated in MECP (2011).

d. The calculation of the soil gas attenuation factor was conducted using the MECP default attenuation factor for residential buildings (2011).

e. The EPC in building is calculated from $C_{building} = C_{sg} * \alpha$.

Notes:

°C = degree Celsius

µg/L = microgram per litre

µg/m^3 = microgram per cubic metre

atm m^3/mol = atmosphere per cubic metre per mole

EPC = exposure point concentration

g/cm^3 = gram per cubic centimetre

J&E = Johnson and Ettinger

L/m^3 = litre per cubic metre

MECP = Ontario Ministry of the Environment, Conservation and Parks

mg/m^3 = milligram per cubic metre

PHC = petroleum hydrocarbon

EPA = U.S. Environmental Protection Agency

Appendix G3
Soil- and Groundwater-to-Outdoor-Air Modelling

APPENDIX G3

Soil- and Groundwater-to-Outdoor-Air Modelling

Estimation of exposure via the soil- and groundwater-to-outdoor-air pathway involves calculating the predicted concentration of contaminant of concern (COC) vapours that result in outdoor air because of the migration of vapours from subsurface soil layers and from groundwater through unsaturated soil into receptor breathing spaces. While the Ontario Ministry of the Environment, Conservation and Parks (MECP) (2011) provides component values for the soil-to-outdoor air pathway (S-OA), the S-OA values are not specifically used in the RA for the following reasons:

- They were derived to be protective of a "cleaned up brownfield" (that is, following the implementation of risk management measures [RMMs]),
- The values only consider vapours from a source in soil, and
- There have been updates to human health inhalation toxicity reference values (TRVs) that may cause some S-OA components to be insufficiently conservative. As the management of vapours traveling to the ground surface and discharging to outdoor air is not typically proposed for redeveloped sites, the application of the most current science in assessing this pathway was preferred in order to provide an appropriately conservative assessment of the potential risk.

The approach for evaluating the outdoor air pathway, described in the following subsections, is intended to evaluate risks to receptors at the RA Property in the existing contaminated condition, not after RMMs have been implemented, from both soil and groundwater vapour sources.

Jury et al. (1990) derived an analytical model that describes the transport of organic compounds through the soil column, including volatilization from the soil surface. The MECP (2011) used the "reduced solution, finite source" version of the Jury model (presented as Equation B1 in Jury et al., 1990) for the derivation of the soil-odour and S-OA component values. Jury et al. (1990) also presents a modified version of this equation which specifically accounts for buried chemicals (presented as Equation B3 in Jury et al. 1990). The form of the equation which can account for buried chemicals is used herein and was adapted by Sanders and Stern (1994) to calculate the flux or emission rate of each individual COC at the boundary between the surface of the soil and ambient air. Both equations assume the following (per MECP 2011):

- No water evaporation or leaching
- Homogeneous soil
- Uniform initial contaminant concentration
- No nonaqueous phase liquid
- No biodegradation
- Instantaneous linear equilibrium adsorption and liquid vapour partitioning

Once the flux has been calculated, a box model (EPA 1989) was then employed as a conservative dispersion model to calculate air concentrations of each predicted COC emission from the soil surface. This model assumes steady-state conditions with instantaneous and complete mixing inside the 'box.' The box has a 13-metre (m) length, a unit width (that is, 1 m), and is bounded at the top by the mixing zone height of 2 m, and, hypothetically, is ventilated by a steady flow of wind across the box. This box size was established to correspond to that of the atmosphere mixing cell described by the MECP (2011). This box volume is considered to conservatively simulate the breathing zone for human receptors in outdoor conditions.

Site-specific wind speed was not available; therefore, for reference purposes, Environment Canada's Canadian Climate Normals (1981 to 2010) for Waterloo Wellington A (Environment Canada 2020) were used. The lowest reported averaged wind speed (August) was 8.5 kilometres per hour (km/hr) and the

annual average wind speed is 12.6 km/hr. For the purposes of this assessment, the conservatively selected wind speed was 8.5 km/hr. For Construction and Utility Workers, it was assumed that, beyond exposure to volatiles in outdoor air above ground surface, these receptors could additionally be exposed to volatiles in outdoor air in an excavated trench. As such, the box could, in fact, be an excavated trench located within the subsurface. The flux of volatiles from the subsurface into a trench would be expected to be greater than that occurring at the surface because the walls of the trench would provide more surface area from which volatiles could discharge. In addition, the enclosed nature of an excavated trench would lead to decreased air exchange and increased potential exposure to subsurface volatiles via inhalation. To account for this scenario, the wind speed applied to the model was reduced to 0.45 metre per second (m/s), which represents the average wind speed in an excavation over a year's time (EPA 1999, MECP Trench Model V.2 [Martinez, pers. comm. 2010]). Additionally, the surface area from which volatiles could flux was increased to 69 m^2 to account for the exposed trench walls, and applying a trench length of 13 m, width of 1 m, and depth of 2 m per the MECP Trench Model V.2 (CCME 2011, Martinez, pers. comm. 2010).

The Site may experience redevelopment in the future. The presence of paving and other surface materials may restrict the flow of soil gases and migration of vapours because the porosity of concrete materials is much less than that for soil. However, for this exposure modelling, and to be conservative, the presence of surface covers was ignored. A coarse-grained soil type was determined to be representative of soil conditions throughout the Site; as such, default "Sand" soil characteristics per EPA (2004) were used to assess the exposure and risk in the absence of RMMs.

The items in Table G3-1 identify the key Site characteristics used as input into the Sanders and Stern (1994) model.

Other conservative assumptions employed in this assessment included the following:

- Degradation of COCs in the soil vadose (unsaturated) zone was not considered to reduce the source concentrations along the transport pathway.
- Bulk water flow and infiltration of precipitation were ignored. Both of these would tend to retard the migration of vapours upward; therefore, they would lead to lower predicted concentrations.

To account for a vapour source in either soil or groundwater, the phase partitioning methods described in MECP (1996) were used to derive a 'total' concentration for COCs in groundwater, including the concentration of a substance in the soil gas phase (air), soil water phase (dissolved), and soil particle phase (absorbed).

For example, concentration on soil particles:

$$C_{SP} = C_{groundwater} \times K_{oc} * f_{oc} \times CF1 \quad (1)$$

Where:

C_{SP} = Concentration on soil particles (microgram per gram [µg/g])

$C_{groundwater}$ = Concentration in groundwater (microgram per litre [µg/L])

K_{oc} = Organic carbon partitioning coefficient (cubic centimetre per gram [cm^3/g])

f_{oc} = Soil organic carbon content (percent)

CF1 = Conversion factor (0.001 litre per cubic centimetre [L/cm^3])

For example, concentration in soil gas:

$$C_{SG} = C_{groundwater} \times K_H \times CF2 \quad (2)$$

Where:

C_{SG} = Concentration in soil gas (µg/m^3)

$C_{groundwater}$ = Concentration in groundwater (µg/L)

K_H = Unitless Henry's Law constant (that is, H/RT)

H = Henry's Law constant (atmospheres per cubic metre per mole [atm-m^3/mol])

R = Universal Gas constant (8.206E-05 atm-m^3/mol per Kelvin [K])

T = Temperature (K) of 288.15, based on a default temperature of 15°C

$CF2$ = Conversion factor (1,000 litre per cubic metre [L/m^3])

Total concentration in soil (µg/g):

$$C_{total} = \frac{C_{groundwater} \times \theta_m \times CF1 + C_{SP} \times \rho_s \times (1-\phi) + C_{SG} \times (\phi - \theta_m) \times CF3}{\rho_b} \quad (3)$$

Where:

ρ_s = Soil particle density (gram per cubic centimetre [g/cm^3])

$CF3$ = Conversion factor (0.000001 cubic metre per cubic centimetre [m^3/cm^3])

$(1 - \phi)$ = Fraction of soil that is solid

$(\phi - \vartheta_m)$ = Air-filled porosity

ϑ_m = Moisture-filled porosity

ρ_b = Dry soil bulk density (gram per cubic centimetre [g/cm^3])

For this assessment, the total predicted concentration in soil based on the estimated maximum groundwater concentration (that is, the observed maximum groundwater concentration plus 20 percent) was compared to the estimated maximum concentration in soil (that is, the observed maximum soil concentration plus 20 percent), and the greater of these two concentrations was applied to model volatilization for outdoor air. The estimated outdoor air concentrations from soil and groundwater above ground surface and in a trench are provided in Tables G3-2 and G3-3, respectively.

Jury et al. (1990) and Sanders and Stern (1994) published the following equation describing the volatilization of organic chemicals from the soil surface as a mass flux:

$$J(t) = C_0 e^{-\mu t}\left(\frac{D_E}{\pi\, t}\right)^{\frac{1}{2}}\left[e^{-\frac{L^2}{4D_E t}} - e^{-\frac{(L+W)^2}{4D_E t}}\right] \quad (4)$$

Where:

J(t) = Instantaneous mass flux rate at any time, t, from soil surface (microgram per square metre per second [µg/m^2/s])

C_0 = Initial contaminant concentration in soil between depth, L, and L+W, where W is the width (that is, the thickness) of the zone of contamination (microgram per cubic centimetre [µg/cm^3]), and $C_0 = C_{total} \times \rho_b$

μ = First-order degradation rate constant (day^{-1}) (calculated based on the half-life value ($t_{1/2}$) if available; where $\mu = \frac{0.693}{t_{1/2}}$; if no half-life was available, assumed no degradation occurs)

t = Time (seconds [s])

D_E = Effective diffusion coefficient (square metres per day [m^2/d])

L = Depth to top of contaminated layer (m)

W = Width of contaminant layer (m)

π = pi (3.14159…)

e = Exponential function

By ignoring bulk water flow and infiltration of precipitation, the model overestimates the vapour flux from the soil.

Effective diffusivity (D_E) (Jury et. al. 1990) was calculated from:

$$D_E = \frac{\left(\frac{a^{\frac{10}{3}} D_a K_H + \theta_m^{\frac{10}{3}} D_w}{\phi^2}\right)}{\rho_b f_{oc} K_{oc} + \theta_m + \theta_v K_H} \quad (5)$$

Where:

ϕ = Total soil porosity (unitless)

θ_m = Residual water content of soil (unitless)

θ_v = Volumetric air content (ϕ-*m*) (unitless)

D_a = Chemical-specific diffusivity in air (m^2/d)

D_w = Chemical-specific diffusivity in water (m^2/d)

K_H = Dimensionless form of Henry's Law constant (unitless)

ρ_b = Dry soil bulk density (g/cm^3)

f_{oc} = Fraction of organic carbon in soil (unitless)

K_{oc} = Chemical-specific organic carbon partitioning coefficient (cubic centimetre per gram [cm^3/g])

The total flux can be determined by integration of the aforementioned flux equation (that is, J(t) = …) and yields the following (Sanders and Stern 1994):

$$TF = \frac{C_0\sqrt{D_E}}{2a}\left\{\left[\exp(2ba)erf\left(ay+\frac{b}{y}\right)+\exp(-2ba)erf\left(ay-\frac{b}{y}\right)\right]_{\sqrt{t_1}}^{\sqrt{t_2}} - \left[\exp(2ca)erf\left(ay+\frac{c}{y}\right)+\exp(-2ca)erf\left(ay-\frac{c}{y}\right)\right]_{\sqrt{t_1}}^{\sqrt{t_2}}\right\} \quad (6)$$

Where:

TF = Total flux per unit area (gram per square metre [g/m^2])

t_1 = Time zero (that is, 0 s)

t_2 = Averaging time for flux, which is greatest early on and decreases rapidly; as such, the averaging time was conservatively set to 25 years to overestimate flux (25 years = 7.884×10^8s)

exp = Exponential function

erf = Error function

Other variables are as described in the previous equation, and as follows:

$$a = \sqrt{\mu} \quad (7)$$

$$b = \frac{L}{2\sqrt{D_E}} \quad (8)$$

$$c = \frac{L+W}{2\sqrt{D_E}} \text{ and} \quad (9)$$

$$y = \sqrt{t} \quad (10)$$

The average flux is determined from the total flux:

$$AF = \frac{TF}{TTxCF} \quad (11)$$

Where:

AF = Average flux from soil surface (µg/m^2/s)

TF = Total flux from soil over assessment period (µg/m^2)

TT = Time period of assessment (years [y])

CF = Conversion factor (31,536,000 seconds per year [s/y])

And the concentration in the receptor's breathing space is calculated by using the box model:

$$C_{air} = \frac{AF \cdot A_r}{W_b \cdot H_b \cdot v_{ws}} \quad (12)$$

Where:

C_{air} = Concentration in outdoor (microgram per cubic metre [µg/m^3])

AF = Average flux from soil surface (µg/m^2/s)

A_r = Area occupied by receptor's box (for surface receptors: 13 m^2; for subsurface receptors: 34.5 m^2, based on a total area of 69 m^2 and a fraction of contaminated area blocked from contributing vapour to the trench of 0.5, as applied in the MECP's Trench Model V.2 referenced in the MECP Rationale Document [2011])

W_b = Width perpendicular to air flow (default: 1 m)

H_b = Height of receptor box (mixing zone) (default: 2 m)

v_{ws} = Wind speed (Site-specific value of 2.36 m/s applied for surface receptors; wind speed in trench of 0.45 m/s applied for Subsurface Workers)

Receptors identified for quantitative assessment of exposure to outdoor air could be exposed to COCs volatilizing from soil and groundwater into outdoor air. Residents, and Outdoor, Construction, Utility, and Indoor Workers could be exposed at the surface; Construction and Utility Workers additionally could be exposed in an excavation. The estimated dose for each receptor was calculated based on receptor characteristics and compared to the reference dose or unit risk, which implies that exposure at that concentration would be continuous over the receptors' lifetime (that is, 24 hours a day, 7 days a week, 52 weeks a year for a lifetime).

Table G3-4 provides a comparison of the approach used to derive the MECP S-OA components and the approach employed in this RA to derive outdoor air concentrations for surface receptors (that is, not in a trench) along with a discussion of uncertainty.

Table G3-4. Soil- and Groundwater-to-Outdoor-Air Pathway Model Uncertainties

Risk Assessment, 200 Beverley Street, Guelph, Ontario

Input Parameter or Assumption	MECP S-OA component Approach (MECP, 2011)	RA Approach	Discussion of Uncertainty
Scenario Considered	Redeveloped brownfield	Existing conditions	The scenarios considered are different. The S-OA components are intended to be used as a check to determine if receptors are at risk outdoors after redevelopment of a property where the S-IA pathway has been blocked, while the intent of the RA approach is to evaluate existing conditions. The RA approach is considered appropriate to determine the risks under current conditions and whether RMMs or other actions (such as remediation) are required for the RA Property.
Vapour Source	Soil	Soil or groundwater	The S-OA component only considers vapour sources from soil. The RA approach considers the greatest vapour contribution from either a soil or groundwater source. Therefore, the RA approach considers more potential vapour sources present at the RA Property than the S-OA component.
Flux Value	Instantaneous flux after 1 year	Average flux over 25 years	The instantaneous flux is greatest early on (based on the time expression in the equation) and then may decrease rapidly. By assuming that 1 year has passed, the peak flux may not be captured by the S-OA component. The approach in this RA averages the flux over a longer duration for the exposure period, which includes the peak flux, which in turn, biases the average emissions to a greater flux, and thus greater potential exposure. The assumptions made for the MECP's S-OA component may not be appropriate for evaluating the existing conditions at the RA Property from long-term exposure. There are uncertainties associated with when the peak flux occurs and when the flux diminishes rapidly as mass is transferred from soil to air. The approach in this RA is considered to be more conservative since it considers a greater emission of the mass from soil.
Depth to Contamination	Assumes volatiles are present at the soil surface (Jury Model)	Assumes a clean layer of soil is present at the soil surface (Modified Jury Model)	The S-OA component assumes that the soil source is present at the soil surface. The RA assumes that a minimal 5 cm "clean" layer is present at the soil surface. This is the primary difference between the two forms of the Jury (1990) equation used in the S-OA approach and the RA approach. This nominal depth was assumed for two reasons: • Releases (or spill) of volatiles to the soil surface causing contaminated soil were assumed to have occurred in the past. Volatilization of COCs from near surface soils would be expected to have occurred following the release due to the proximity of the COCs to the surface soil air boundary layer, or • Fill soils may have been imported to the site and placed on top of historical volatiles impacts. The model's sensitivity to the depth input was tested by changing the 5 cm "clean" thickness to a 1 mm "clean" thickness (that is, essentially assuming the contamination is present at the surface, similar to the S-OA method assumption). On average, the final ground surface air concentrations increased by approximately 1 percent when the

Table G3-4. Soil- and Groundwater-to-Outdoor-Air Pathway Model Uncertainties

Risk Assessment, 200 Beverley Street, Guelph, Ontario

Input Parameter or Assumption	MECP S-OA component Approach (MECP, 2011)	RA Approach	Discussion of Uncertainty
			contamination was assumed to be present at the surface compared to the 5 cm clean layer assumption. The difference in final air concentrations is considered negligible and does not affect the overall results and conclusions of the RA. The uncertainties associated with the RA approach is the depth to contamination which can be highly variable. Contamination at surface would be limited to the area of a release, with other areas having a clean layer over top of a migrating subsurface plume. The use of a nominal clean layer of 5 cm is not likely to underestimate the actual emissions of volatile COCs.
Mixing Cell Dimensions	13 m by 2 m by unit width	13 m by 2 m by unit width	The mixing cell dimensions are the same between the two approaches.
Windspeed	8.5 km/hr Based on long-term average annual windspeed at Waterloo Wellington A	City- or Region-specific Based on nearest available lowest reported windspeed data	The MECP uses a fixed windspeed based on an annual average. The RA uses a site-specific windspeed based on a lowest reported windspeed. Therefore, the RA approach is considered conservative, and is likely to overestimate outdoor air concentrations and risk. The uncertainty associated with selecting the lowest observed windspeed is likely to over estimate exposure.

Appendix H
Toxicity Profiles

APPENDIX H

Toxicological Profile for Anthracene

Background Information

Anthracene belongs to the group of compounds called polycyclic aromatic hydrocarbons (PAHs). Natural sources of PAHs include: forest fires, volcanic activity, and agricultural burning, while anthropogenic sources include: industry and energy production facilities, vehicular sources, and domestic heating. There are over 100 individual PAH compounds, but PAHs typically occur as chemical mixtures. PAHs are used to make medicine, dyes, plastics, pesticides, and asphalt. They are also present in crude oil, coal, coal tar pitch, creosote, and roofing tar (ATSDR 1995).

Exposure pathways for PAHs typically include air, water, food, and soil via inhalation, ingestion, and dermal exposure routes. Inhalation is likely to be a major source of intake, as some PAHs can bind to particles and dust in the air, while others occur as vapours. Cigarette smoke is an important exposure pathway for PAH, as are vehicle exhaust in urban areas and wood smoke. The exposure to PAHs in food is also a major source of intake, as PAHs are frequently present in cereals, produce, meat, processed food, dairy products, and barbecued foods (ATSDR 1995).

Assessment of Carcinogenicity

With the lack of human data and inadequate animal data for anthracene, the U.S. Environmental Protection Agency (EPA) has classified the parameter as a Classification D carcinogen, "not classifiable as to human carcinogenicity" (2009).

Selection of Noncarcinogenic Inhalation Exposure Limits

Table 1 summarizes the noncancer inhalation exposure limits for anthracene.

Table 1. Noncancer Inhalation Exposure Limits for Anthracene

Regulatory Agency	Exposure Limit (mg/m^3)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
MADEP (2004) (based on TPHCWG [1997])	0.05	Chronic	Body weight reduction, hepatic, renal, and developmental effects	• **Basis:** Based on TPHCWG (1997), as cited in MADEP (2003) for Aromatic hydrocarbons containing 9 through 18 carbons. • **Notes:** MADEP (2003) recommends an RfC of 0.05 mg/m^3 for aromatic fraction (C9-C18) based on the evaluation of RfCs identified for individual components and fractional mixtures.	Yes

Notes:
MADEP = Massachusetts Department of Environmental Protection
mg/m^3 = milligram(s) per cubic metre
RfC = reference concentration
TPHCWG = Total Petroleum Hydrocarbon Working Group

The MECP does not provide an inhalation RfC value. Although anthracene is not a volatile organic chemical, an inhalation exposure was evaluated as a conservatively protective approach in the RA assessment.

Selection of Carcinogenic Inhalation Exposure Limits

The MECP, ATSDR, and EPA do not provide exposure limits for cancer health effects resulting from oral exposure to anthracene.

APPENDIX H

Toxicological Profile for Antimony

Antimony is a silvery white brittle metal which can be found in small amounts in the earth's crust and can be measured in natural soils, sediments, and water (ATSDR, 2019; Health Canada, 1999).

Antimony ores are mined and then either changed into antimony metal or combined with oxygen to form antimony oxide (ATSDR, 2019). Antimony is used to manufacture alloys with tin, lead, and copper, and in the compounding of pesticides, ammunitions, disk-brake pads, cutting disks, and fireworks. As a hardening alloy, antimony is used for storage batteries, bullets, cable sheaths, bearing metal, type metal solder, collapsible tubes, foil, and sheet and pipe metal. It is combined with chlorides as coloring agents and as catalysts, and with fluorides in organic synthesis and pottery manufacture (ATSDR, 2019).

Pure antimony is used in the production of semiconductors, infrared detectors, and diodes, but seldom found in this form (Health Canada, 1999). Antimony is more likely to be found as trivalent and pentavalent sulphides or chlorides.

Soluble pentavalent antimony (antimony[V]) compounds (sodium stibogluconate, stibosamine) are used as specific therapeutics against different forms of leishmaniasis and are physiologically tolerated more than trivalent antimony (antimony[III]) compounds. Antimony potassium tartrate (APT) (tartar emetic) has been used to induce vomiting in poisoning cases, and antimony compounds, such as piperazine antimony tartrate, were used as drugs against bilharzia (WHO DW, 2003).

Exposure pathways for antimony in environmental media include air, water, food, and urban dust via inhalation, ingestion, and dermal exposure routes. Antimony concentrations have been shown to be higher in urban air than in nonurban air, most likely because of the larger number of emission sources present in urban areas (ATSDR, 2019).

Assessment of Carinogenicity

The International Agency for Research on Cancer (IARC, 1989) has concluded that there is inadequate evidence for the carcinogenicity of antimony trisulfide and antimony trioxide (ATO) in humans but sufficient evidence of carcinogenicity in experimental animals for ATO and limited evidence for the carcinogenicity of antimony trisulfide in experimental animals. ATO was assigned to Group 2B (possibly carcinogenic to humans), and antimony trisulfide to Group 3 (not classifiable as to its carcinogenicity to humans) (WHO DW, 2003). The USEPA has not evaluated antimony for the carcinogenicity potential, and thus has not classified antimony (USEPA, 1987).

Selection of Non-Carcinogenic Oral Exposure Limits

Table 1 summarizes the non-cancer oral exposure limits.

Table 1. Non-cancer Oral Exposure Limits

Regulatory Agency	Exposure Limit (mg/kg/day)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
MECP, 2011 from USEPA IRIS, 1987	4.0E-04 (RfD)	Chronic	Longevity, blood glucose, and cholesterol (rat)	• **Basis:** Schroeder et al., 1970 • **Study Design:** 5 ppm of potassium antimony tartrate was administered to 50 male and 50 female rats in drinking water throughout their lifespan • **POD:** LOAEL of 5 ppm (0.35 mg/kg/day) • **UF:** 1000 (10 for interspecies conversion, 10 to protect sensitive individuals, and 10 for the LOAEL instead of NOEL)	No
RIVM, 2009 and WHO, 2003	6.0E-03 (TDI)	Subchronic	Decreased body weight, food and water intake (rats)	• **Basis:** Poon et al., 1998 and Lynch et al., 1999 • **Study Design:** Antimony potassium tartrate was administered (0, 0.5, 5.0, 50, and 500 ppm antimony) via drinking water in rats over a 90-day exposure period • **POD:** NOAEL of 50 ppm (6 mg/kg/day) • **UF:** 1,000 (100 for intra- and interspecies variation and 10 for the use of a subchronic study) • **Notes:** According to Lynch et al. (1999, as referenced in RIVM, 2009), the histological changes observed at low-dose levels were not considered signs of overt toxicity and were often identified without a dose-relationship. WHO (2003) and RIVM (2009) both considered the suggested NOAEL (Lynch et al., 1999) from the subchronic drinking-water study in rats conducted by Poon et al. of 6.0 mg/kg/day based on decreased body weight gain and reduced food and water intake.	Yes

Notes:

LOAEL = lowest observed adverse effect level
NOAEL = no observed adverse effect level
POD = point of departure
ppm = parts per million
RfD = reference dose
TDI = tolerable daily intake
UF = uncertainty factor

As discussed in RIVM (2009), several limitations in methodology and control data of the Schroeder et al. (1970) study were noted in a review by Lynch et al. (1999). Examples of the limitations of these studies include comparisons made between test and control groups from different studies and different ages. Lynch et al. (1999) also noted that a high rate of death from viral pneumonia in rats may have influenced the conclusions regarding reduced lifespan. Additionally, no detailed histopathological examination was performed in the mouse study. Based on this, Lynch et al. (1999) concluded that the Schroeder et al. (1970) rat study that administered antimony potassium tartrate (APT) via drinking water was unsuitable for the derivation of a health-based guidance level.

The WHO DW (2003) and RIVM (2009) derivations are based on subchronic effects from the Poon et al. (1998) study. While the derivation of the RfD presented in USEPA (1987) is based on chronic effects from the Schroeder et al. (1970) study, there is low confidence in the Schroeder et al. study for the following reasons:

- Only one species and dose level were used
- No NOAEL was determined
- Gross pathology and histopathology were not well described (USEPA, 1987)

Additionally, when the USEPA (1987) oral TRV was derived, confidence in the database was low due to a lack of adequate oral exposure investigations.

Although it was a subchronic study, the Poon et al. (1998) study, on which the adopted RfD was based, incorporates multiple exposure concentrations, whereas the Schroeder et al. study only incorporated a single exposure concentration. For this reason, the Poon et al. (1998) study is preferred to the Schroeder et al. (1970) study. Based on the rationale presented above, the Poon et al. (1998) study, and the NOAEL of 6 mg/kg/d, is considered the most appropriate for the selection of an oral noncancer TRV for antimony in this RA. A total UF of 1,000 is supported due to the study limitations; therefore, the non-carcinogenic oral TRV derived by WHO (2003) and RIVM (2009) of 6.0E-03 mg/kg/d is selected for antimony.

APPENDIX H

Toxicological Profile for Benzene

Background Information

Benzene, also known as benzol, is a highly volatile, flammable, colourless liquid with a sweet odour. It is found in the atmosphere, water, and soil from both industrial and natural sources (ASTDR 2007). Derived from petroleum, benzene is ranked in the top 20 in production volume for chemicals produced in the United States (U.S.). It is used in various industries for the manufacturing of styrene (for plastics), cumene (for various resins), and cyclohexane (for nylon and synthetic fibres), in addition to the manufacturing of some types of rubber, lubricant, dyes, detergents, drugs, and pesticides. Although there are natural sources of benzene (from gas emissions from volcanoes and forest fires), the primary source is anthropogenic emissions from industrial processes, such as from burning coal and oil, motor vehicle exhaust, and evaporation from gasoline service stations. Leakage from underground storage tanks or from landfills can contaminate groundwater. Benzene is not known to bioaccumulate in plants or animals; however, benzene is soluble in water and can pass through the soil into groundwater, then volatilize into air (ASTDR 2007).

Exposure pathways for benzene include air, water, food, and soil via inhalation, ingestion, and dermal exposure routes. Inhalation is the major source of benzene exposure by the general population. Major inhalation sources include tobacco smoke, automobile service stations, vehicular exhaust, and industrial emissions. Vapours (or gases) from products that contain benzene, such as glues, paints furniture wax, and detergents, can also be a source of exposure. The level of exposure to benzene by ingestion through food, beverages, or drinking water is not as high through exposure by vapours (ATSDR 2007).

Assessment of Carcinogenicity

The U.S. Environmental Protection Agency (EPA), the International Agency for Cancer Research, and the Department of Health and Human Services have identified benzene as a carcinogen (as cited in the ATSDR 2007).

Selection of Noncarinogenic Inhalation Exposure Limits

Table 1 summarizes the noncancer inhalation exposure limits for benzene.

Table 1. Noncancer Inhalation Exposure Limits

Regulatory Agency	Exposure Limit (mg/m^3)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
MECP (2011) EPA IRIS (2003) (derived from Rothman et al. [1996])	3.0E-02 mg/m^3	Chronic	Decreased lymphocyte count	• **Basis:** Derived from the BMD modelling of ALC data from the occupational epidemiologic study by Rothman et al. (1996, as reported in EPA IRIS [2003]). • **POD:** NOAEL from the Ward et al. (1985, as reported in EPA IRIS [2003]) subchronic experimental animal inhalation study. • **Study Design:** Identified a dose-related decrease in absolute lymphocyte count.	No
ATSDR (2007) (derived from	9.6E-03 mg/m^3	Chronic	Decreased lymphocyte count	• **Basis:** Occupation study by Lan et al. (2004) based on decreased lymphocyte count following inhalation exposure by workers.	Yes

Table 1. Noncancer Inhalation Exposure Limits

Regulatory Agency	Exposure Limit (mg/m^3)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
Lan et al. [2004])				• **Study Design:** 390 workers at two shoe factories exposed to benzene at levels below the U.S. occupational standard of 1 ppm were observed. Benzene-exposed workers were categorized into four exposure groups (control, <1 ppm, 1 to 10 ppm, >10 ppm). • **POD:** BMCL of 0.03 ppm for decreased B cell counts.	

Note:
NOAEL = no observed adverse effect level

The US EPA IRIS (2003) reference concentration (RfC) was based on an occupational study by Rothman et al. (1996), which identified a dose-related decrease in absolute lymphocyte count. Similarly, ATSDR (2007) used an occupational exposure study by Lan et al. (2004), which identified a dose-related decrease in B-cell counts. The study by Lan et al. (2004) had a larger study population and more exposure groups than Rothman et al. (1996), and included lesser exposure concentrations. As a result of the lesser exposure concentrations, the Lan et al. (2004) LOAEL is over 10-fold less than the LOAEL in Rothman et al. (1996). These factors provide more confidence in ATSDR's TRV.

Selection of Carcinogenic Inhalation Exposure Limits

The MECP (2011) unit risk factor of 2.2E-03 was selected for use in this RA.

APPENDIX H

Toxicological Profile for Cadmium

Background Information

Cadmium (Cd) is a naturally occurring element in the earth's crust that forms both organic and inorganic compounds, but is usually found as a mineral combined with other elements such as oxygen, chloride, and sulphur (ATSDR 2012). All soils and rocks, including coal and mineral fertilizers, contain some cadmium. Most cadmium is extracted during the production of other metals (for example, copper, lead, and zinc). Cadmium does not corrode easily and has many uses, including batteries, pigments, metal coatings, and plastics. Cadmium is released into the environment through the burning of coal and other fossil fuels, and is also present in tobacco smoke. Volcanic emissions contain cadmium-enriched aerosols.

The main target organs for cadmium toxicity are the kidneys, gastrointestinal tract, and lungs (ORNL 1991; ATSDR 2012). Occupational exposure to high levels of cadmium in air can severely damage the lungs and may lead to death. The inhalation or oral exposure to lower levels of cadmium for prolonged periods of time can result in a buildup of cadmium in the kidneys, and if sufficiently high, may result in kidney disease. The oral ingestion (for example, food and drinking water) of high levels of cadmium severely irritates the stomach, leading to vomiting and diarrhea, and sometimes death. Oral exposure to lesser levels of cadmium for a prolonged period of time can also cause bones to become fragile and break easily. There is some evidence from animal studies that cadmium can be toxic to developing foetuses (for example, decreased foetal weight, and teratogenic and neurological effects).

Assessment of Carinogenicity

Health Canada Canadian Environmental Protection Act (CEPA) (1994) and International Agency for Research on Cancer (IARC) (1993) have classified cadmium and cadmium compounds as human carcinogens, concluding there was sufficient evidence for cadmium to produce lung cancer in humans and animals exposed by inhalation.

Selection of Noncarcinogenic Oral Exposure Limits

Table 1 summarizes the noncancer oral exposure limits.

Table 1. Noncancer Oral Exposure Limits

Regulatory Agency	Exposure Limit (mg/kg/day)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
MECP (2011)	3.2E-05 (RfD)	Chronic	Renal toxicity (humans)	• **Basis:** Modified from CalEPA DW (2006) • **Study Design:** Review of toxicokinetic studies in human males to estimate long-term daily oral cadmium intake associated with urinary cadmium levels of 1 µg/g creatinine after 50 years • **POD:** NOAEL of 19 µg/day • **UF:** 50 (5 for sensitive populations, 10 for cancer risk due to oral exposure) • **Notes:** A relative source contribution of 20% was applied to derive a Public Health Goal of 0.04 µg/L	No
ATSDR (2012)	1.0E-04 (MRL)	Chronic	Renal toxicity (humans)	• **Basis:** Buchet et al. (1990), Suwazono et al. (2006), Järup et al. (2000), Kobayashi et al.	Yes

Table 1. Noncancer Oral Exposure Limits

Regulatory Agency	Exposure Limit (mg/kg/day)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
				(2006), Shimizu et al. (2006), Jin et al. (2004), Wu et al. (2001) • **Study Design:** Meta-analysis of 7 environmental exposure dose-response (human) studies estimating internal dose corresponding to probabilities of 10% excess risk of low molecular weight proteinurea. • **POD:** The dietary concentration in females (0.33 µg/g) associated with the 95% lower confidence limit of urinary cadmium dose of 0.5 µg/g creatinine • **UF:** 3 for human variability	
Health Canada (2010)	1.0E-03 (TDI)	Chronic	Renal toxicity (humans)	• **Basis:** Health Canada (1986) Guideline for Canadian Drinking Water Quality and Friberg et al. (1971) epidemiological study • **Study Design:** Epidemiological study of workers exposed to cadmium oxide dusts and/or fumes • **POD:** NOAEL of 2.5 µg Cd/g creatinine in urine • **UF:** None • **Notes:** The provisional tolerable weekly intake of 7 µg/kg/week was maintained, which is equivalent to 1 µg/kg/d or 1.0E-03 mg/kg/d.	No
EPA (1989) (same as CalEPA [2000])	1.0E-03 (RfD)	Chronic	Renal toxicity (human and animal)	• **Basis:** EPA (1985) • **Study Design:** Evaluation of multiple human and animal toxicity studies • **POD:** NOAEL of 0.01 mg/kg/day resulting in 200 µg Cd/g wet human renal cortex (i.e., highest renal level not associated with significant proteinuria) • **UF:** 10 for intrahuman variability • **Notes:** This RfD is for food intake assuming 2.5% adsorption of Cd from food	No

Notes:
% = percent
µg = microgram(s)
µg/g = microgram(s) per gram
µg/day = microgram(s) per day
µg/kg/day = microgram(s) per kilogram per day
µg/kg/week = microgram(s) per kilogram per week
µg/L = microgram(s) per litre
ATSDR = Agency for Toxic Substances and Disease Registry
CalEPA = California Environmental Protection Agency
Cd/g = cadmium per gram
DW = drinking water
EPA = U.S. Environmental Protection Agency
MECP = Ontario Ministry of the Environment, Conservation and Parks
mg/kg/d = milligram(s) per kilogram per day
MRL = minimal risk level
NOAEL = no observed adverse effect level
POD = point of departure
RA = risk assessment
RfD = reference dose
TDI = tolerable daily intake
UF = uncertainty factor

The ATSDR (2012) chronic oral minimal risk level (MRL) of 1.0E-04 mg/kg/d has been adopted as the chronic noncancer toxicity reference value (TRV) over the use of the MECP's (2011) recommended chronic RfD. This was based on the ATSDR (2012)'s robust comparable analysis of the POD data with a lower

uncertainty factor (UF) of 3 than the UF of 50 of the CalEPA DW (2006) evaluation. Similarly, the Health Canada (2010) oral TDI and EPA (1989) oral RfD were not selected because the ATSDR (2012) chronic oral MRL was based on a more robust analysis of more recent exposure studies.

Selection of Carcinogenic Oral Exposure Limits

EPA (1989) classified cadmium as B1 "probable human carcinogen" by inhalation, but determined oral animal studies have not shown evidence of a carcinogenic response. The National Institute of Public Health and the Environment (RIVM) (2001) also concluded the evidence for carcinogenic properties by the oral route is insufficient. Since the evidence for carcinogenic properties by the oral route is insufficient and the Health Canada and CalEPA oral slope factors (SFs) were derived by route-to-route extrapolation from inhalation, these TRV derivations were not considered appropriate for selection. Therefore, no SF is provided.

APPENDIX H

Toxicological Profile for 1,1 Dichloroethane

Background Information

The production and use of 1,1-dichloroethane (1,1-DCA) as a solvent, cleaning agent and degreaser, and its use in the manufacturing of 1,1,1-trichloroethane; vinyl chloride; plastic wrap; and synthetic fibre may result in its release to the environment. It is a colourless, oily liquid with a chloroform-like odour. 1,1-DCA can be released into the air, water, and soil at places where it is produced or used as a solvent. Human exposure can occur from the air, water, or consumer products. 1,1-DCA is highly volatile based on its vapour pressure and Henry's Law constant, and has low bioaccumulation potential (ATSDR 2015).

1,1-DCA is a chlorinated aliphatic chemical. Exposure to 1,1-DCA can occur from the inhalation of air containing 1,1-DCA, and may cause central nervous system depression and irritation to the skin or respiratory tract. Historically, 1,1-DCA was used as an anesthetic; however, due to the risk of cardiac arrhythmia induction in humans at anesthetic doses (approximately 26,000 parts per million[ppm]), this was discontinued (ATSDR 2015).

Assessment of Carinogenicity

Based on numerous studies there is inconclusive evidence on the carcinogenicity of 1,1-DCA. While the U.S. Environmental Protection Agency (EPA) has classified 1,1-DCA as a possible human carcinogen, neither the Department of Health and Human Services nor the International Agency for Research on Cancer have classified the carcinogenic potential of 1,1-DCA (ATSDR 2015)

Selection of Noncarcinogenic Oral Exposure Limits

Table 1 summarizes the noncancer oral exposure limits.

Table 1. Noncancer Oral Exposure Limits for 1,1 Dichloroethane

Regulatory Agency	Exposure Limit (mg/kg/day)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
EPA PPRTV (2006)	2.0E-01 (RfD)	Chronic	Renal toxicity in rats	• **Basis:** Muralidhara et al. (2001) • **Study Design:** A gavage study exposed male Sprague-Dawley rats for 13 weeks to an array of doses (as referenced in EPA PPRTV [2006]). • **POD**: NOAEL of 714.3 mg/kg/day • **UF:** UF 3,000 (10 for subchronic to chronic, 10 interspecies extrapolation, 10 for human variability, and 3 for database deficiencies)	Yes
EPA PPRTV (2006)	2.0 (RfD)	Subchronic	Renal toxicity in rats	• **Basis:** Muralidhara et al. (2001) • **Study Design:** A gavage study exposed male Sprague-Dawley rats for 13 weeks to an array of doses (as referenced in EPA PPRTV [2006]). • **POD**: NOAEL of 714.3 mg/kg/day • **UF:** UF 300 (10 interspecies extrapolation, 10 for human variability, and 3 for database deficiencies)	Yes

Table 1. Noncancer Oral Exposure Limits for 1,1 Dichloroethane

Regulatory Agency	Exposure Limit (mg/kg/day)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
CalEPA DW (2003)	4.0E-02 (RfD)	Chronic	Kidney damage in cats	• **Basis:** Hofmann et al. (1971) • **Study Design:** An oral study where cats were exposed to 500 ppm of 1,1,-DCA for 13 weeks, followed by an additional 13 weeks at 1,000 ppm. • **POD:** NOAEL of 40 mg/kg/day • **UF:** 1,000 (10 for inter species differences, 10 for intraspecies differences, and 10 for sub-chronic to chronic extrapolation)	No
MECP (2011) (from CalEPA DW [2003])	4.0E-01 (RfD)	Subchronic	Kidney damage in cats	• **Basis:** Hofmann et al., 1971 • **Study Design:** An oral study where cats were exposed to 500 ppm of 1,1,-DCA for 13 weeks, followed by an additional 13 weeks at 1,000 ppm. • **POD:** NOAEL of 40 mg/kg/day • **UF:** 1,00 (10 for inter species differences and 10 for intraspecies differences)	No

Notes:
CalEPA = California Environmental Protection Agency
DW = drinking water
MECP = Ontario Ministry of the Environment, Conservation and Parks
mg/kg/day = milligram(s) per kilogram per day
NOAEL = no observed adverse effect level
POD = point of departure
PPRTV = Provisional Peer Reviewed Toxicity Values
RA = risk assessment
RfD = reference dose
UF = uncertainty factor

The MECP (2016) recommended the use of the EPA PPRTV (2006)-proposed RfD of 2E-01 mg/kg/day. The CalEPA RfD (previously selected by the MECP) was based on a 13-week inhalation study, while the EPA PPRTV RfD was based on a 13-week oral study. The use of a route-specific exposure study is preferred; therefore the selected RfD and subchronic RfD was based on the EPA PPRTV.

Selection of Carcinogenic Oral Exposure Limits

Table 2 summarizes the cancer oral exposure limits.

Table 2. Cancer Oral Exposure Limits for 1,1 Dichloroethane

Regulatory Agency	Exposure Limit (mg/kg/day)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
CalEPA DW (2009)	5.7E-03 (SF)	Chronic	Mammary gland adenocarcinomas in rats	• **Basis:** Gold et al. (1984); NCI (1977) • **Study Design:** Gold et al. (1984) lists the NCI (1977) results of the oral gavage studies for male and female rats and mice. Doses of 350 mg/kg to up to 1,800 mg/kg in rats and 900 mg/kg to 3600 mg/kg in mice, were administered once per day, 5 days a week, for 78 weeks. • **Notes:** POD and UF were not available in the Cal EPA document	Yes

Notes:
mg/kg = milligram(s) per kilogram
SF = slope factor

The MECP, Health Canada, EPA Integrated Risk Information System (IRIS), and ATSDR do not provide evaluation for cancer health effects resulting from oral exposure to 1,1-DCA. However, the CalEPA (2009) included a cancer SF for oral exposures to 1,1-DCA of 5.7E-03 mg/kg/day. This cancer SF is based on female rat mammary gland adenocarcinoma tumor data and cross-route extrapolation methods (Gold et al. 1984, as reported in CalEPA DW 2009), and is also used by EPA in derivation of the regional screening levels (RSL) (EPA 2016).

Selection of Noncarinogenic Inhalation Exposure Limits

The MECP (2011) reference concentration (RfC) of 0.17 milligram per cubic metre (mg/m^3) has been selected for use in this RA.

Selection of Carcinogenic Inhalation Exposure Limits

Table 3 summarizes the carcinogenic inhalation exposure limits for 1,1 DCA.

Table 3. Carcinogenic Inhalation Exposure Limits for 1,1 Dichloroethane

Regulatory Agency	Exposure Limit $(mg/m^3)^{-1}$	Toxicological Endpoint	Study Details	Selected for Use in the RA
CalEPA DW (2003)	1.6E-03 (IUR)	Female rat mammary gland adenocarcinoma tumor	• **Basis:** Gold et al. (1984); NCI (1977) • **Study Design:** Goled et al. (1984) lists the NCI (1977) results of the oral gavage studies for male and female rats and mice. Doses of 350 mg/kg to up to 1800 mg/kg in rats and 900 mg/kg to 3,600 mg/kg in mice, were administered once per day, 5 days a week, for 78 weeks. • **Notes:** POD and UF were not available in the Cal EPA document	Yes

Note:
IUR = inhalation unit risk

The MECP, Health Canada, EPA IRIS, and ATSDR do not provide evaluation for cancer health effects resulting from inhalation exposure to 1,1-DCA. The EPA unit risk factor (CalEPA 2009) of 1.6E-03 per mg/m^3 was selected for this RA based on female rat mammary gland adenocarcinoma tumors. This value is also used by EPA in derivation of the RSLs (EPA 2016).

APPENDIX H

Toxicological Profile for Fluorene

Background Information

Fluorene is a lighter polycyclic aromatic hydrocarbon (PAH) with three benzene rings. It exists as a white crystalline solid and is almost insoluble in water, but is soluble in a number of organic solvents, including: ether, benzene, and carbon disulphide (Budavari et al., 1989, as referenced in Agency for Toxic Substances and Disease Registry [ATSDR], 1995). Fluorene can be produced from coal tar or by the reduction of diphenyl ketone with zinc (Oak Ridge National Laboratory [ORNL], 1994). It is used as a chemical intermediate in various applications, in the formation of polyradicals for resins, and in the manufacture of dyestuffs. Fluorene occurs naturally in fossil fuels and is found in coal tars, products of incomplete combustion, vehicle emissions, and mainstream cigarette smoke – where it is the second most abundant PAH. Fluorene is a major component of the total PAH content in the environment. Human exposure to fluorene occurs primarily through smoking tobacco, inhaling polluted air, and ingesting food and water contaminated by combustion effluents (International Agency for Research on Cancer [IARC], 1983). Fluorene has been detected in soils, groundwater, and surface waters at a number of hazardous waste sites in the United States (ATSDR, 1995).

Assessment of Carcinogenicity

The USEPA (USEPA, 1990) classified fluorene as a Group D substance – not classifiable as to human carcinogenicity. This classification was based on a lack of human data and inadequate data from animal bioassays.

The International Agency for Research on Cancer (IARC) (1983) has classified fluorene as a Group 3 substance – not classifiable as to its carcinogenicity to humans.

Selection of Non-Carinogenic Inhalation Exposure Limits

Table 1 summarizes the noncancer inhalation exposure limits for cadmium.

Table 1. Non-cancer Inhalation Exposure Limits for Fluorene

Regulatory Agency	Exposure Limit (mg/m^3)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
MADEP, 2004	5E-02	Chronic	CNS effects and increased liver and kidney weight.	• **Basis:** Based on a mixture study wherein rats were exposed to high flash aromatic naphtha by inhalation (Clark et al., 1989, as referenced in MADEP 2003). • **Study Design:** Derived an RfC value of 5.0E-02 mg/m^3 as a surrogate toxicity value for constituents of the C_9 to C_{18} aromatic TPH fraction (which includes fluorene). The parameters used to assess toxicity included: body and organ weight, clinical observations, and hematology and serum chemistry. • **POD:** The NOAEL was identified by MADEP (2003) as 9.0E02 mg/m^3 (adjusted to 160 mg/m^3 for continuous exposure) based on hepatic and central nervous system effects.	Yes

Table 1. Non-cancer Inhalation Exposure Limits for Fluorene

Regulatory Agency	Exposure Limit (mg/m^3)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
				• **UF:** 3000 (10 for use of a subchronic study for chronic RfC derivation, 10 each for inter- and intra-species variability, and 3 for database deficiencies)	
TPHCWG, 1997	2.0E-01	Chronic	Increased liver and kidney weight	• **Basis:** Based on a rat study by Clark et al. (1989) • **Study Design:** Rats were exposed to concentrations of 0, 450, 900, or 1,800 mg/m^3 for 6 hours per day, 5 days per week for one year. An increase in liver and kidney weights at the highest dose were identified as the sensitive endpoints of the study • **POD:** NOAEL of 900 mg/m^3 • **UF:** 1000 (10 most sensitive, 10 animal to human, and 10 sub-chronic to chronic)	No

Notes:

LOAEL = lowest observed adverse effect level

mg/m^3 = milligram per cubic metre

MRL = minimal risk level

NOAEL = no observed adverse effect level

POD = point of departure

RfC = reference concentration

TPH = total petroleum hydrocarbon

UF = uncertainty factor

Because the MADEP (2003) recommended RfC of 0.05 mg/m^3 for c_9 to c_{18} fraction is more conservatively protective, it is selected for use in this RA.

APPENDIX H

Toxicological Profile for Iron

Background Information

Iron is a naturally-occurring element in minerals found in the earth's crust. Iron is a metal that is alloyed with carbon, manganese, chromium, nickel, and other elements to form steels. The primary use of direct-reduced iron is as a clean supplement that replaces the ferrous scrap charge in high quality-oriented electric arc furnace steelmaking. Iron is an essential element in the body. Exposure to iron may occur through handling of iron ores or iron compounds where it is mined or used (HSDB, 2009).

The Hazardous Substances Databank (HSDB) (2009) and United States Environmental Protection Agency (EPA) Provisional Peer Reviewed Toxicity Value (PPRTV) toxicological profile (2006) present the toxicokinetics for iron. In humans and other animals, iron levels in the body are regulated primarily through changes in the amount of iron absorbed by the gastrointestinal mucosa. The absorption of dietary iron is influenced by body stores, by the amount and chemical nature of iron in ingested food, and by a variety of dietary factors that increase or decrease the availability of iron for absorption. Ferrous iron is transported across intestinal mucosal cells by active transport with the rate of transport inversely related to body iron stores. Depending on the iron status of the body, stored iron is bound to ferritin within mucosal cells and macrophages in the liver, spleen, and bone, or is transported in the plasma bound to transferrin. Although iron absorption is regulated, excessive accumulation of iron in the body resulting from chronic ingestion of high levels of iron cannot be prevented by intestinal regulation, and humans do not have a mechanism to increase excretion of absorbed iron in response to elevated body levels (EPA, 2006).

Assessment of Carcinogenicity

The EPA (2006) PPRTV and International Agency for Research of Cancer have not evaluated iron for its carcinogenicity.

Selection of Noncarcinogenic Oral Exposure Limits

Table 1 summarizes the noncancer oral exposure limits.

Table 1. Noncancer Oral Exposure Limits for Iron

Regulatory Agency	Exposure Limit (mg/kg/day)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
EPA, 2021; EPA, 2006	0.7	Acute	Gastrointestinal effects (Humans)	• **Basis:** Frykman et al. (1994) • **Study Design:** Evaluated the adverse effects of daily oral therapy with iron fumarate in a double-blind, crossover, placebo-controlled study in Swedish male [n=25; mean age 45 years (range 40-52)] and female [n=23; mean age 41 years (range 34-45)] adult blood donors. Study subjects were administered 60 milligrams (mg) elemental iron as a daily dose of iron fumarate for 1 month, with each study subject serving as their own placebo control. • **POD:** LOEL of 60 mg/kg/day • **UF:** 1.5 (use of minimal LOAEL)	Yes

Table 1. Noncancer Oral Exposure Limits for Iron

Regulatory Agency	Exposure Limit (mg/kg/day)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		

Notes:
LOAEL = lowest observable adverse effect level
mg/kg/day = milligram(s) per kilogram per day
POD = point of departure
RA = risk assessment
UF = uncertainty factor

The Ontario Ministry of the Environment, Conservation and Parks (MECP) (2011) did not provide any oral toxicity reference values (TRVs) for iron. Therefore, an oral RfD of 0.7 mg/kg/day was selected from EPA (2006) PPRTV.

Selection of Carcinogenic Oral Exposure Limits

The EPA PPRTV and International Agency for Research of Cancer have not evaluated iron for its carcinogenicity.

APPENDIX H

Toxicological Profile for Mercury

Background Information

Mercury occurs naturally in the environment and exists in several forms organized into three categories: metallic or elemental mercury, inorganic mercury, and organic mercury. This toxicological profile supports the toxicological reference values (TRVs) selected for inorganic and elemental mercury.

Elemental mercury is the only element to be liquid at room temperature. It is heavier than water, and is shiny, silver-white, odourless, and naturally occurring. (ATSDR, 2001). Mercury exposure Some uses of this type of mercury are production of chlorine gas; the extraction of gold from ore; and the production of thermometers, thermostats, fluorescent light bulbs, batteries, and dental fillings.

Assessment of Carinogenicity

The U.S. Environmental Protection Agency (EPA 1995a) classified mercury as a Group D substance – not classifiable as to human carcinogenicity. This classification was based on inadequate human and animal data. The International Agency for Research on Cancer (IARC) (1993) has classified metallic and inorganic mercury as a Group 3 substance – not classifiable as to its carcinogenicity to humans. The IARC concluded there is inadequate evidence for the carcinogenicity of mercury in humans, and there is limited evidence on experimental animals.

Selection of Noncarinogenic Inhalation Exposure Limits

Table 1 summarizes the noncancer inhalation exposure limits for mercury.

Table 1. Noncancer Inhalation Exposure Limits

Regulatory Agency	Exposure Limit (mg/m^3)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
EPA RSL (2012); EPA IRIS (1995a)	3.0E-04 (RfC)	Chronic	Neurophysiological effects (Humans)	• **Basis:** Based on various occupational studies (Fawer et al. [1983]; Piikivi [1989]; Piikivi and Hanninen [1989]; Piikivi and Tolonen [1989]; Ngim et al. [1992]; Liang et al. [1993], as referenced in EPA [1995a]) • **Study Design:** These studies involved inhalation exposure to mercury (air concentrations, 0.0008 to 0.042 mg/m^3; blood levels, 10 to 12 µg/L; urine levels – 17 to 20 µg/L) in occupational settings for average duration ranging from 5.5 years to 15.8 years • **POD:** LOAEL of 0.025 mg/m^3 based on studies by Fawer et al. (1983), Ngim et al. (1992), and Liang et al. (1993) • **UF:** 30 (10 for intraspecies variation, and 3 for lack of database, particularly developmental and reproductive studies) • **Notes:** Air concentrations were extrapolated from blood levels based on the conversion factor and description in studies of Roels et al. (1987), Piikivi (1989), Piikivi and	No

Table 1. Noncancer Inhalation Exposure Limits

Regulatory Agency	Exposure Limit (mg/m^3)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
				Hanninen (1989), and Piikivi and Tolonen (1989).	
MECP, 2011 (from CalEPA ChREL [2000])	9.0E-05 (RfC)	Chronic	Nervous system	• **Basis:** Based on various occupational studies (Fawer et al. [1983]; Piikivi [1989]; Piikivi and Hanninen [1989]; Piikivi and Tolonen [1989]; Ngim et al. [1992]; Liang et al. [1993], as referenced in EPA [1995a]) • **Study Design:** These studies involved inhalation exposure to mercury (air concentrations, 0.0008 to 0.042 mg/m^3; blood levels, 10 to 12 µg/L; urine levels – 17 to 20 µg/L) in occupational settings for average duration ranging from 5.5 years to 15.8 years • **POD:** LOAEL of 0.025 mg/m^3 based on studies by Fawer et al. (1983), Ngim et al. (1992), and Liang et al. (1993) • **UF:** 100 • **Notes:** Air concentrations were extrapolated from blood levels based on the conversion factor and description in studies of Roels et al. (1987), Piikivi (1989), Piikivi and Hanninen (1989), and Piikivi and Tolonen (1989).	No
CalEPA, 2014	3.0E-05 (RfC)	Chronic	Nervous system; development; kidney (Humans)	• **Basis:** Based on various occupational studies (Fawer et al. [1983]; Piikivi [1989]; Piikivi and Hanninen [1989]; Piikivi and Tolonen [1989]; Ngim et al. [1992]; Liang et al. [1993], as referenced in EPA [1995a]) • **Study Design:** These studies involved inhalation exposure to mercury (air concentrations, 0.0008 to 0.042 mg/m^3; blood levels, 10 to 12 µg/L; urine levels – 17 to 20 µg/L) in occupational settings for average duration ranging from 5.5 years to 15.8 years • **POD:** LOAEL of 0.025 mg/m^3 based on studies by Fawer et al. (1983), Ngim et al. (1992), and Liang et al. (1993) • **UF:** 300 (3 for intraspecies variation, 10 for LOAEL, and 10 for susceptibility of children) • **Notes:** Air concentrations were extrapolated from blood levels based on the conversion factor and description in studies of Roels et al. (1987), Piikivi (1989), Piikivi and Hanninen (1989), and Piikivi and Tolonen (1989).	Yes

Notes:

µg/L = microgram(s) per litre

ChREL =

mg/m^3 = milligram(s) per cubic metre

RfC = reference concentration

RSL = Regional Screening Level

Since the CalEPA value is more recent and reinterpreted from the same agency and source study as the MECP (2011) selection, the CalEPA (2014) inhalation RfC for elemental or metallic mercury was used in

this RA. The inhalation RfC derived by CalEPA (2014) was based on the same studies considered by USEPA IRIS (1995b) and MECP (2011), however CalEPA (2014) used a more conservative approach, as it accounted for a larger uncertainty factor. The CalEPA (2000) RfC adopted by the MECP (2011) was derived with an UF of 100, and was later revised by CalEPA to use an UF of 300 to account for "greater susceptibility among children". While the USEPA IRIS (1995b) based its RfC on the same study, a lower UF was used (30), and therefore a less conservative RfC was derived.

APPENDIX H

Toxicological Profile for 2-(1-)Methylnaphthalene

Background Information

2-(1-)Methylnaphthalene (2-methylnaphthalene or 1-methylnaphthalene) are naphthalene-like compounds. 1-Methylnaphthalene is liquid, and 2-methylnaphthalene is solid. 2-Methylnaphthalene is used to make vitamin K. 1-Methylnaphthalene and 2-methylnaphthalene are used to make other chemicals, such as dyes and resins; both are present in cigarette smoke, wood smoke, tar, asphalt, and at some hazardous waste sites (ATSDR 2005).

Exposure to 2-(1-)methylnaphthalene may occur primarily through breathing air containing it. The release of methylnaphthalene in air occurs from burning wood or fossil fuel, automobile exhaust, and cigarette smoke. Low-level exposure to methylnaphthalene may also occur by drinking water or accidentally eating soil or inhaling dust that contains 2-(1-)methylnaphthalene (ATSDR 2005).

Assessment of Carinogenicity

Under the U.S. Environmental Protection Agency's (EPA's) *Draft Revised Guidelines for Carcinogen Risk Assessment* (1999), the data regarding the carcinogenicity of 2-methylnaphthalene in mice and the lack of human carcinogenicity data are inadequate to assess human carcinogenic potential.

Selection of Noncarinogenic Inhalation Exposure Limits

Table 1 summarizes the noncancer inhalation exposure limits for 2-(1-)methylnaphthalene.

Table 1. Noncancer Inhalation Exposure Limits for 2-(1-)methylnaphthalene

Regulatory Agency	Exposure Limit (mg/m^3)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
MADEP (2003)	0.05 (RfC)	Chronic	CNS effects and increased liver and kidney weight	• **Basis:** Clark et al. (1989) • **Study Design:** This study exposed male rats to high flash aromatic naphtha vapors at 0, 450, 900, or 1,800 mg/m^3, 6 hours/day, 5 days/week for 12 months. • **POD:** NOAEL of 900 mg/m^3 • **UF:** 3,000 (10 for animal to human extrapolation, 10 for human variability, 10 for subchronic to chronic extrapolation, and 3 for database deficiency) • **Notes:** NOAEL was adjusted for continuous exposure (900 mg/m^3 x 6 hours/24 hours x 5 days/7 days = 160)	Yes

Notes:

LOAEL = lowest observed adverse effect level
MADEP = Massachusetts Department of Environmental Protection
NOAEL = no observed adverse effect level
POD = point of departure
RfC = reference concentration
UF = uncertainty factor

The MECP, Health Canada, EPA, and Agency for Toxic Substances and Disease Registry (ATSDR) do not provide evaluation for noncancer health effects resulting from inhalation exposure to 2-(1-)methylnaphthalene. However, MADEP provides an inhalation reference concentration for 2-methylnaphthalene (2003), which is used in the RA.

Selection of Carcinogenic Inhalation Exposure Limits

The data regarding the carcinogenicity of 2-methylnaphthalene in mice and the lack of human carcinogenicity data are inadequate to assess human carcinogenic potential (EPA 1999).

APPENDIX H

Toxicological Profile for n-Hexane

Background Information

n-Hexane is a straight-chain, fully saturated hydrocarbon with six carbon atoms; it is also referred to as hexane and hexyl hydride, and is made from crude oil. Pure n-Hexane is a colourless liquid with a slightly disagreeable odour. It evaporates very easily into the air and dissolves only slightly in water. n-Hexane is highly flammable, and its vapours can be explosive. It is a solvent that has many uses in the chemical and food industries, either in pure form or as a component of a mixture. It is used for the extraction of edible fats and oils from crops, such as soybeans; and as cleaning agents in textile and shoe making, furniture manufacturing, and in the printing industry. n-Hexane is the solvent base for many commercial products, such as glues, rubber cements, paint thinners, and degreasers. It comprises about 11.6 percent of unleaded gasoline and about 2 percent of JP-4 aviation fuel (ATSDR 1999; EPA 2005a).

Exposures to n-Hexane can occur from the inhalation of air containing n-Hexane, and through skin by dermal contact with n-Hexane-containing products. Per the Agency for Toxic Substances and Disease Registry (ATSDR) (1999), "some occupational groups that may be exposed to n-Hexane include refinery workers, shoe and footwear assembly workers, laboratory technicians, workers operating or repairing typesetting and printing machinery, construction workers, carpet layers, carpenters, auto mechanics and gas station employees, workers in plants manufacturing tires or inner tubes, and workers in air transport and air freight operations." Products in the home containing n-Hexane can also be responsible for exposure if ventilation is not adequate (ATSDR 1999).

Assessment of Carcinogenicity

The U.S. Environmental Protection Agency (EPA) concluded there is inadequate information to assess the carcinogenic potential of n-Hexane. Specifically, there are no available animal carcinogenicity studies examining exposure to n-Hexane, and there is a single human study. The available studies for humans and laboratory animals are inadequate for cancer risk assessment (EPA 2005a and 2005b). The International Agency for Research on Cancer (IARC) did not classify n-Hexane for its carcinogenicity.

Selection of Noncarcinogenic Oral Exposure Limits

Table 1 summarizes the noncancer oral exposure limits.

Table 1. Noncancer Oral Exposure Limits for n-Hexane

Regulatory Agency	Exposure Limit (mg/kg/day)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
EPA HEAST (1997)	6.0E-02 (RfD)	chronic	Nervous system neuropathy; testicular atrophy	• **Basis:** RfD from the subchronic gavage study by Krasavage et al. (1980, as referenced in EPA [1997 and 2005a]; ATSDR [1999]). • **Study Design:** The gavage study exposed male rats to n-hexane of a 90 day period, five days per week. Groups of five rats were exposed to doses of 0, 6.6, 13.2, and 46.2 mmol/kg (570 mg/kg/day) of n-Hexane over the study period. The rats in the 46.2 mmol/kg group, had an increased observation and exposure period of 120 days to ensure that an overt neuropathological endpoint was detected.	Yes

Table 1. Noncancer Oral Exposure Limits for n-Hexane

Regulatory Agency	Exposure Limit (mg/kg/day)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
				The appearance of hind limb paralysis and giant axonal swellings were observed in the high-dose group, indicating a neuropathy endpoint. • **POD:** Neuropathy LOAEL of 570 mg/kg/day • **UF:** 10,000	
EPA HEAST (1997)	6.0E-01 (RfD)	sub-chronic	Nervous system neuropathy; testicular atrophy	• **Basis:** RfD from the subchronic gavage study by Krasavage et al. (1980, as referenced in EPA [1997 and 2005a]; ATSDR [1999]). • **Study Design:** The gavage study exposed male rats to n-hexane of a 90 day period, five days per week. Groups of five rats were exposed to doses of 0, 6.6, 13.2, and 46.2 mmol/kg (570 mg/kg/day) of n-Hexane over the study period. The rats in the 46.2 mmol/kg group, had an increased observation and exposure period of 120 days to ensure that an overt neuropathological endpoint was detected. The appearance of hind limb paralysis and giant axonal swellings were observed in the high-dose group, indicating a neuropathy endpoint. • **POD:** Neuropathy LOAEL of 570 mg/kg/d • **UF:** 1,000	Yes

Notes:

HEAST = Health Effects Assessment Summary Tables
LOAEL = lowest observed adverse effect level
mg/kg/day = milligram(s) per kilogram per day
mmol/kg = millimole(s) per kilogram
POD = point of departure
RfD = reference dose
UF = uncertainty factor

The Ontario Ministry of the Environment, Conservation and Parks (MECP) (2011) did not provide any oral toxicity reference values (TRVs) for n-Hexane. Therefore, a provisional chronic oral RfD of 6.0E-02 mg/kg/day and subchronic RfD of 6.0E-01 mg/kg/day were selected from EPA's HEAST from 1997.

Selection of Carcinogenic Oral Exposure Limits

The MECP, Health Canada, EPA, and ATSDR do not provide cancer health effects based toxicity criteria from oral exposure to n-Hexane.

Selection of Noncarinogenic Inhalation Exposure Limits

Table 2 summarizes the noncancer inhalation exposure limits for cadmium.

Table 2. Noncancer Inhalation Exposure Limits for n-Hexane

Regulatory Agency	Exposure Limit (mg/m^3)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
MECP (2011), based on MECP 24-hour AAQC (2005)	2.5	Chronic	-	• **Basis:** The MECP's 24-hour AAQC. • **Notes:** Additional information regarding the basis of the MECP selection of this value is not available. However, the AAQC's are values protective of adverse effects to health and environment from air contaminants. Additional averaging periods of 1 hour and 10 minutes are available as AAQC guidelines for hexane.	No
EPA IRIS (2005a and 2005b)	7.0E-01	Chronic	Neurotoxic effects (functional impairment of the peripheral nervous system).	• **Basis:** Based on study by Huang et al. (1989, as referenced in EPA [2005a and 2005b]) on male Wistar rats. • **Study Design:** Rats were exposed to 0, 500, 1,200, or 3,000 ppm (0, 1,762, 4,230, 10,574 mg/m^3) n-Hexane (greater than 99 percent pure) for 12 hours per day, 7 days per week for 16 weeks. • **POD:** A reduction in body weight gain, MCV, grip strength, and motion were observed and a NOAEL of 500 ppm identified. • **UF:** 300 • **Notes:** The data from this study set provided an adequate dose response for benchmark dose modelling with an estimated point of departure of a benchmark concentration limit/human equivalent concentration of 215 mg/m^3.	Yes

Notes:
AAQC = ambient air quality criteria
IRIS = Integrated Risk Information System
mg/m^3 = milligram(s) per cubic metre
NOAEL = no observed adverse effect level
ppm = part(s) per million

An inhalation TRV of 7.0E-01 mg/m^3 was selected for n-Hexane based on the reference concentration (RfC) value provided by EPA IRIS. An inhalation TRV provided in the MECP guidance is not selected as it is based on ambient air quality standard, whereas the EPA value is derived based on dose-response studies and standard methods to derive the RfC.

Selection of Carcinogenic Inhalation Exposure Limits

The MECP, Health Canada, EPA, and ATSDR do not provide cancer health effects based toxicity criteria from inhalation exposure to n-Hexane.

APPENDIX H

Toxicological Profile for Phenanthrene

Background Information

Phenanthrene belongs to the compound group called polycyclic aromatic hydrocarbons (PAHs). PAHs are emitted as byproducts of incomplete combustion and pyrolysis of organic matter. Natural sources of PAHs include forest fires, volcanic activity, and possibly, biosynthesis; while anthropogenic sources include industry and energy production facilities, vehicle emissions, and domestic heating. In North America, mobile emission sources are considered the primary emissions sources of PAH. PAHs are also produced during cooking and processing food. There are over 100 individual PAH compounds, but PAHs typically occur as chemical mixtures. PAHs are used to make medicine, dyes, plastics, pesticides, and asphalt. They are also present in crude oil, coal, coal tar pitch, creosote, and roofing tar (ATSDR 1995).

Exposure pathways for PAHs typically include air, water, food, and soil via inhalation, ingestion, and dermal exposure routes. Inhalation is likely to be a major source of intake, as some PAHs can bind to particles and dust in the air, while others occur as vapours. Cigarette smoke is an important exposure pathway for PAHs, as well as vehicle exhaust in urban areas and wood smoke. Exposure to PAHs in food is also a major source of intake, as PAHs are frequently present in cereals, produce, meat, processed food, dairy products, and barbecued foods (ATSDR 1995).

Phenanthrene and anthracene are both tricyclic PAHs, which influences their behaviour and mechanism of action.

Assessment of Carinogenicity

The International Agency for Research on Cancer (IARC) (1999) has classified phenanthrene as Group 3, not classifiable as to carcinogenicity. The U.S. Environmental Protection Agency (EPA) classifies phenanthrene in Group D, not classifiable as to human carcinogenicity (1997).

Selection of Noncarcinogenic Oral Exposure Limits

Table 1 summarizes the noncancer oral exposure limits.

Table 1. Noncancer Oral Exposure Limits for Phenanthrene

Regulatory Agency	Exposure Limit (mg/kg/day)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
RIVM (2001)	4E-02 (RfD)	-	Applicable to the noncarcinogenic C9 to C16 aromatic TPH fraction (or its constituents), and based on decreased body weight and increased kidney and liver weight.	• **Notes:** The RIVM (2001) derived an oral chronic RfD of 4.0E-02 mg/kg/day based on evaluation of total petroleum hydrocarbons (TPHCWG, 1997) for noncarcinogenic aromatic compounds with equivalent carbon numbers >C9 to C16 (that is, anthracene, fluorene, naphthalene and phenanthrene). Additional details regarding the development of this RfD are not readily available; therefore, confidence in this RfD is low due to a lack of supporting documentation.	Yes

Notes:

mg/kg/day = milligram(s) per kilogram per day

RA = risk assessment

RfD = reference dose

RVIM = Netherlands National Institute for Public Health and Environmental

TPH = total petroleum hydrocarbon

TPHCWG = Total Petroleum Hydrocarbon Criteria Working Group

The Ontario Ministry of the Environment, Conservation and Parks (MECP) and other regulatory agencies including Health Canada, Agency for Toxic Substances Disease Registry (ATSDR), and EPA Integrated Risk Information System (IRIS) do not provide exposure limits for noncancer health effects resulting from oral exposure to phenanthrene. Although the RIVM (2001) toxicological reference value (TRV) is not based on toxicological data specific to phenanthrene, there are a lack of suitable human and animal data for this chemical. No oral chronic noncancer reference concentration values for phenanthrene have been derived by any of the authoritative bodies reviewed; hence, the use of the RfD value of 4.0E-02 mg/kg/day derived by RIVM (2001) was selected for use as a conservative approach in this RA.

Selection of Carcinogenic Oral Exposure Limits

The ATSDR, EPA, and Health Canada do not provide exposure limits for cancer health effects resulting from oral exposure to phenanthrene.

Selection of Noncarinogenic Inhalation Exposure Limits

Table 2 summarizes the noncancer inhalation exposure limits for Phenanthrene.

Table 2. Noncancer Inhalation Exposure Limits for Phenanthrene

Regulatory Agency	Exposure Limit (mg/m^3)	Toxicological Basis		Study Details	Selected for Use in the RA
		Exposure Duration	Endpoint		
MADEP (2004)	5E-02 (RfC)	-	CNS effects, and increased liver and kidney weight	• **Notes:** The MADEP (2004) provides an inhalation RfC value of 5.0E 02 mg/m^3 based on evaluation of TPHs (TPHCWG 1997) for non-carcinogenic aromatic compounds with equivalent carbon numbers >C9 to C16 (that is, anthracene, fluorene, naphthalene and phenanthrene). Additional details regarding the development of this RfC are not readily available; therefore, confidence in this RfD Cs low due to a lack of supporting documentation.	Yes

Notes:
CNS =
MADEP = Massachusetts Department of Environmental Protection
mg/m^3 = milligram(s) per cubic metre
RfC = reference concentration

Due to the lack of human and animal studies, the ATSDR, EPA IRIS, Health Canada, and MECP do not provide noncancer inhalation RfCs following exposure to phenanthrene.

Although the MADEP (2004) TRV is not based on toxicological data specific to phenanthrene, there are a lack of suitable human and animal data for this chemical. No inhalation noncancer reference concentration values for phenanthrene have been derived by any of the authoritative bodies reviewed; hence, the use of the RfC value of 5.0E-02 mg/m3 derived by MADEP (2004) was selected for use as a conservative approach in this RA.

Selection of Carcinogenic Inhalation Exposure Limits

The ATSDR, EPA, and Health Canada do not provide exposure limits for cancer health effects resulting from inhalation exposure to phenanthrene.

m^3	cubic metre(s)
MECP	Ontario Ministry of the Environment, Conservation and Parks
mm	millimetre(s)
MNRF	Ontario Ministry of Natural Resources and Forestry
NAPL	non-aqueous phase liquid
PP	polypropylene
PVC	polyvinyl chloride
QP	Qualified Person
RA	Risk Assessment
RMM	risk management measure

Appendix I. Engineered Risk Management Measures

This engineering report is intended to support the Risk Management Plan as discussed in Section 7 of the RA main text. It presents the conceptual design of the engineered risk management measures (RMMs):

- Physical barriers (hard caps and fill caps) to eliminate risk associated with direct exposure of human and ecological receptors to impacted soil that will remain on the RA Property.
- Vapour intrusion (VI) controls to eliminate or manage risks associated with human exposure via the potential migration of contaminants into the indoor air of buildings, where required.

I.1 Physical Barriers

Contact with impacted soils currently present at the RA Property may result in unacceptable risks to human and ecological receptors. The fundamental approach to managing the risk is to block the contact by instituting physical barriers between both human and ecological receptors and the underlying impacted soils. Upon redevelopment of the RA Property, a physical barrier (either a fill or hard cap) is required across the entire Site. The type of physical barriers that will be required at the RA Property depends on their compatibility with the redevelopment plans. Physical barriers can involve one or more of the following broader categories:

- Hard caps
- Fill caps
- Utility corridors

Specific site design has not been finalized at this stage of the project; consequently, conceptual designs for physical barrier systems have been developed. These conceptual physical barrier specifications provide a basis of design for likely construction scenarios, and the designers will refine the conceptual designs, as needed, during preparation of site-specific plans, which will be verified by a Qualified Person (QP).

The cap designs discussed herein are not intended to limit or prevent surface water infiltration to mitigate leaching of contaminants from shallow, unsaturated soils. Infiltration of surface water was not identified as requiring risk management.

I.1.1 Hard Caps

Hard caps can be used for walkways, parking areas, driveways, and other purposes on the RA Property. Common hard cap materials include:

- Armour stone
- Asphalt
- Cobbles
- Concrete
- Grates
- Pavers (permeable, pervious, or porous)
- Paving stones
- Rubberized surfaces
- Other materials that are resistant to erosion and burrowing animals

The thickness of the hard cap layer required depends on the physical characteristics of the material selected, such as:

- Cracking
- Resistance to mechanical damage
- Vandalism
- Weathering
- Other effects that will result in exposure of the underlying contaminated soils

The thickness of the hard cap layer will be 75 mm. The layer will be underlain by a structural base material (granular "A" or equivalent) of minimum thickness of 150 mm for a total minimum thickness of 225 mm. Unimpacted fill may consist of soil located on the RA Property that meets the Fill Cap Target Concentrations (FCTC) as developed in the RA or imported soil that meets the Table 6 Site Condition Standards (SCS) as per Ontario Regulation 153/04 (MECP, 2011).

Structural or geotechnical considerations will determine the type of structural base material and unimpacted fill and the installed thickness (which may be greater than the minimum requirements). Figure I-1 illustrates a typical profile of a hard cap application.

It is expected that some minor cracking will occur, as is typical of hard surface treatments, such as asphalt and concrete. Provided the surface material is not entirely compromised, the underlying structural base layer will provide additional isolation from the underlying impacted soils until repairs are required. The barrier material should be stable and resistant to frost heave, settlement, or other wear that would necessitate frequent repair.

I.1.2 Fill Caps

In areas where ~~there are potential risks to terrestrial plants, soil invertebrates, birds, and small mammals, and~~ the land use requires unconsolidated material for vegetation growth, a fill cap consisting of unimpacted fill ~~should~~ can be used as the RMM. Fill cap thickness varies depending upon use, whether it will support vegetation, and if so, the type of plants to be grown in a specific area. Figures I-2 illustrate typical profiles of fill cap applications. Fill caps for community land will be maintained regularly as part of general site maintenance activities.

The following materials are defined as unimpacted fill:

- Soil located on the RA Property may be used as unimpacted fill on the RA Property provided it meets the FCTC (Table 7-2c) developed as part of this RA. Soil that meets the FCTC can remain in place as part of the fill cap, or be placed on existing impacted soils.
- Soil located off the RA Property considered for importation to the RA Property as unimpacted fill must meet the applicable generic Table 6 SCS.
- Granular materials, such as Granular A, Granular B, and crushed stone from a virgin source (that is, a commercial sand and gravel pit or quarry licensed by the Ontario Ministry of Natural Resources and Forestry [MNRF])
- Inert non-soil materials, such as crushed concrete that has been deemed suitable by a Qualified Person (QP), as necessary
- Commercial landscaping products, such as compost, bark chips, fertilizer, or other such products

When unimpacted fill is a blend of materials, professional judgement should be used to determine whether the blended material or only the soil component is analyzed for comparison to FCTC.

Table I-1 outlines a typical example of required fill cap thicknesses based on plant type. Typical profiles for fill cap applications are illustrated on Figure I-2.

Table I-1. Example Requirements for Fill Cap Thickness for Plantings

Risk Assessment, 200 Beverley Street, Guelph, Ontario

Vegetation Type [a]	Fill Cap Thickness (Minimum) [b, c]	Figure
Manicured Lawn or Grass	1,000 mm	I-2
Shrubs and Wildflowers	1,000 mm	I-2
New Trees [d]	1,500 mm to mature tree dripline or 3-m radius from tree trunk (whichever is greater) and 1,500 mm beyond	I-3~~, Detail 1~~
~~Existing Trees [d]~~	~~150 mm protective layer to mature tree dripline or 3-m radius from tree trunk (whichever is greater) and 1,500 mm beyond~~	~~I-3, Detail 2~~

[a.] Examples of vegetation type include manicured lawn or grass, shrubs, wildflowers and perennials, and new ~~and existing~~ trees.

[b.] Soil cap thickness requirements can be achieved by confirming presence of existing unimpacted fill over existing impacted soil, by placing additional unimpacted fill to make up thickness, or by excavating impacted soil to the desired cap thickness and backfilling with unimpacted fill to the existing elevation. Minimum fill cap barrier thickness depends on the vegetation type as shown on Table I-1. Once the development plans are established, a MECP Qualified Person for Environmental Site Assessments (QP_{ESA}) should confirm that the cap thicknesses are appropriate for the intended future use.

[c.] Fill cap barrier thickness may be increased by a landscape architect to reflect the specific types of vegetation (that is, rooting depths) to be planted on a site-specific or area-specific basis.

[d.] New trees will only be planted in areas containing a minimum soil cap thickness of 1,500 mm. ~~For existing trees that will not be removed, a 150-mm protective layer will be installed over the impacted soil to prevent human and ecological exposure.~~ Refer to Section I.1.3 for further details.

Notes:

m = metre(s)
mm = millimetre(s)

The minimum fill cap thicknesses required for other scenarios are specified in the following subsections.

I.1.3 Fill Caps around Trees

The existing trees at the RA Property have been naturally established along the property boundaries and between the remaining floor slabs due to the vacant condition of the Site. It is not anticipated that any of the trees currently existing at the RA Property will be retained as part of any redevelopment activities. Trees considered to be tolerant to urban conditions have root systems varying from shallow and wide-spreading to deep. Most of a tree's roots typically grow within the top 60 centimetres (cm) of the surface and are not usually found deeper than 1 to 1.5 m in good quality, well-drained, and uncompacted soil (City of Toronto, 2016; AECOM, 2009). Certain species of mature deep-rooted trees may extend deeper than 1.5 metres below ground surface (mbgs) which may, in limited areas of the Site, periodically reach the water table during wetter periods of the year. The root system can extend to more than two to three times the dripline distance of a tree. If a barrier thickness of 1,500 mm is considered by a landscape architect or certified arborist to be insufficient for the tree species rooting depth, then consideration should be given to alternate tree selection or compaction of the subgrade to minimize downward growth of roots. Also, if an alternate cap depth is considered sufficient, which may be the case for tree installations in Silva Cells, then the cap depth may be adjusted. For areas that include new trees, a minimum 1,500 mm (fill barrier and protective layer) is required to address the risk of dermal contact, support tree growth, and

adequately isolate roots from impacted subgrade, as depicted in Figure I-3. The fill materials must meet the FCTC (or Table 6 SCS for imported soil), support plant growth, and be deemed suitable by a QP and landscape architect. Selection of species of trees as part of future landscape plans must also consider the possibility of limited and periodic root system contact with the water table and potential contact with contaminants (specifically PHC, PAHs and zinc).

~~Consistent with the use of the dripline for existing trees, t~~The lateral extent of the minimum 1,500-mm fill cap for newly planted trees should extend to the expected width of the tree canopy at maturity, or to the extent of Silva Cells if used in tree planting, or to 3-m radius from the tree trunk, whichever is greater. This coincides with the 2013 recommendation that individually planted trees each need a minimum of 30 cubic metres (m^3) of soil to produce larger, healthier trees (DTAH et al., 2013). In areas where hardscaping will be installed around trees, pavers (permeable, pervious, or porous) or grates may be used to provide free passage of precipitation and air.

I.1.4 Utility Corridors

Utility corridors can provide a preferential path for contaminated groundwater, volatile, or non-aqueous phase liquid (NAPL) transport. To mitigate contaminant transport along the utility trench, several construction approaches can be used, though each is subject to minor infiltration or deterioration over time. The following approaches are options for mitigating migration along utility corridors:

- Trench plugs: Commonly used and comprise low-permeability materials
- Anti-seep collars: Barriers made of any rigid impermeable material, such as concrete, steel, or geomembranes
- Trench liner: Impermeable liner placed at the bottom and sides of utility trenches
- Watertight shoring: Shoring at the walls should be supplemented by lining the bottom of the trench with impermeable liner or low-permeability materials

Where new utilities in areas of impacted groundwater or impacted soil are connected to existing City utilities or enclosed structures, trench mitigation measures should be installed, except in the following instances, which do not require trench mitigation measures:

- Utilities installed above the high groundwater level
- Utilities less than 1 m deep
- Utilities that are directionally drilled

Of the previously described trench mitigation measures, trench plugs are most commonly used; and for these, the low-permeability barrier should be installed across the trench cross-section (extending ["keyed"] into the existing soils at least 300 mm at the base and sides of the trench) to prevent migration of contaminants in groundwater or soil vapour in the permeable backfill material along the buried piping, conduit, or duct banks. A conceptual design for a trench block, such as a trench plug or anti-seep collar, is presented on Figure I-4. Trench plugs should consist of compacted clay or bentonite, or other low-permeability material, such as concrete or unshrinkable fill. Clay seals should be compacted at appropriate moisture contents (i.e., at or on the plus side of the clay's optimum moisture content) and extend for a minimum length of 750 mm along the utility trench and across its full width. The trench plug should extend from the base of the trench to above the high groundwater level, and at least 1,000 mm above the top of the utility, or up to the base of the overlying cap barrier, whichever is greater.

Also, where existing utilities in areas of impacted soil are connected to new utilities, trench mitigation measures, such as low-permeability barriers, should be installed in the transition section of the new utility.

I.1.5 Equivalency

Cap or barrier materials can be replaced by any other cap or barrier materials that meet the FCTC, or that is clean material from a virgin source (that is, from a sand and gravel pit or MNRF-licensed quarry). In addition, the barrier must meet the dimensional requirements for separation from the existing impacted soils specified in Section I.1.

I.2 Vapour Intrusion Mitigation

As discussed in Section 7.2.1 of the RA, VI measures for mitigating indoor air inhalation risks are required for all future occupied buildings that meets the requirement of the Ontario Building Code.

The redevelopment design plans for the RA Property have not yet been confirmed/developed. Consequently, the designs for vapour mitigation systems presented in this document are conceptual, taking into consideration typical building and VI mitigation scenarios. The conceptual designs incorporate three key elements:

1. Passive venting systems, including subslab, submembrane, suction pits (or plenum boxes), and vapour cutoff trenches
2. Vapour proof barriers
3. Foundation and penetration sealing

All VI mitigations shall include at minimum a vapour proof barriers plus a passive venting system.

Conceptual designs for these three key RMM types are presented herein. The conceptual designs will be refined during preparation of building-specific plans, taking into consideration the type of building and whether the foundation will be in contact with groundwater.

I.2.1 Venting System Conceptual Design

The venting system is intended to act as a pressure-relief, collection, and venting system that will dilute soil vapours in contact with the foundation, in addition to collecting and venting those vapours away from the structure. A conceptual design for passive venting (applicable to a slab-on-grade or subgrade foundation) is illustrated in cross-section and plan views on Figures I-5 and I-6, respectively. The plan-view orientation illustrates a general layout of the pressure relief, collection, and venting components. Final orientation and coverage (that is, whether the entire building footprint or just a portion of the building requires venting) will depend on the identified vapour mitigation needs. Venting component orientation should account for structural elements, including footings, piles, piers, foundation drainage systems, building envelope components, utility and site servicing infrastructure, and any other aspects of site redevelopment that may be relevant.

The venting systems will operate in a passive manner, providing pressure relief, collection, and venting of soil vapours that may be present under or near the building foundation. Soil vapour is collected and conveyed away from the building footprint and vented to the atmosphere primarily because of pressure-induced gas flow. The operation of the system has the effect of diluting the vapour concentrations in contact with the foundation.

If the venting system is located within the footprint of the building, it will be connected to vent risers that exit to the exterior building, as illustrated on Figure I-7 under unsaturated and saturated conditions. It is likely that future subgrade structures at the RA Property will require depths that may involve saturated conditions, given the shallow depth to groundwater. This condition and integration with long-term

groundwater management will need to be considered in the final design. Since it is a restriction that NAPL be removed prior to permitting subgrade occupied structures within the NAPL area (Figure 7-2), it is not anticipated that NAPL will be in direct contact with the foundation. However, appropriate consideration must be given to the material selection for these systems in a saturated groundwater environment that may include various chemical constituents at concentrations between the applicable generic O. Reg 153/04 standards and the PSSs for the RA Property.

The vent risers will be at least 100 mm in diameter, and are typically constructed of Schedule 40 (minimum) polyvinyl chloride (PVC). The discharge end of the vent risers will be completed with a pipe return bend and insect screen. Alternatively, the outlet can be outfitted with a rotary wind turbine, which will impart a slight passive vacuum to the venting system when wind-driven operation occurs.

The following is recommended for the positioning of vent risers to mitigate potential exposure to venting vapours by outdoor receptor:

- 0.9 m above the roof line
- 0.9 m away from any parapet
- 1.2 m away from any property line
- 1.5 m away from any electrical device
- 3.0 m above grade
- 3.0 m away from any windows, doors, roof hatch, opening, or air intake into the building

Actual design of the vent risers should take into consideration diffusion modeling of the venting emission. Additionally, vent risers should be oriented around the foundation perimeter to avoid vapour discharge being drawn into building ventilation systems.

The venting layer should be composed of a system of perforated collection piping within a coarse-grained layer comprising coarse sand, pea gravel, clear crushed stone, or a geosynthetic three-dimensional vent core product that provides equivalent venting performance over the design life of the building. The collection pipes will be a minimum 100-mm diameter and are typically constructed of Schedule 40 (minimum) PVC. Pipe joints will be threaded or rubber-gasket bell and spigot, but not solvent welded.

The venting system components must be sufficiently permeable to allow unimpeded flow of soil vapour. Pipe perforations will be holes (13 mm maximum diameter) or slotted, providing a minimum open area of 5,000 square millimetres per linear metre (mm^2/lin.m). Horizontal separation of the collection pipes and the distribution of the collection pipes will be determined at the time of site-specific building design based on the system capacity, properties of the bedding and cover material, soil conditions underneath the building, and VI mitigation needs of the building.

Both during construction and in the long term, the permeability of the venting components must not be reduced by fine-grained material, building materials, concrete, or water entering the layer components; geotextile filter fabric may need to be incorporated into the building-specific barrier system design to achieve this requirement. A nonwoven geotextile layer will be installed under and over the venting system components before construction.

Soil vapour monitoring ports may be integrated into each of the vent risers, to monitor vapour concentrations collected via the venting system. As described in Section 7.4.1 of this RA, monitoring of the performance of the VI system may require the sampling of subslab vapour, through installation of subslab vapour pins. The combination of monitoring both subslab vapour in conjunction with the vent riser ports provides evaluation of the performance of the venting system.

The components of the passive venting system should be constructed so the system may be made active if VI RMM monitoring (outlined in Tables 7-7 and 7-8) indicates the VI RMM is not effective in a passive configuration. An active venting system works in the same conceptual manner as a passive system; however, vapour collection and venting are enhanced using fans or blowers that increase air exchange volumes. The size and number of fans or blowers that may be needed if a system is converted to an active system will depend on the size and configuration of the structure, and will be specified once the building design has been finalized. Piping for the passive venting system is to be installed so the purchase and installation of the fan or blower can be completed, if required, based on the findings of the baseline performance assessment.

Venting layer depressurization systems should be able to create a vacuum of 4 Pascals (Pa) or greater to overcome barometric pressure fluctuations.

I.2.2 Vapour-proof Barrier Conceptual Design

I.2.2.1 Background and Criteria

The ability of a material to retard the diffusion of vapour is measured by units known as "perms." Permeance is defined in ASTM International (ASTM) D1079-10, *Standard Terminology Relating to Roofing and Waterproofing*, as the rate of vapour per unit area at a steady state through a membrane or assembly, expressed in nanogram per second per square metre per Pascal (ng/Pa.s.m^2) (or in grains - square feet per hour per inch of mercury [ft^2.hr.in.Hg] for imperial units) or unit of perms.

There are numerous ASTM methods for determining permeance. Typical methods used are ASTM E96/E96M-10, *Standard Test Methods for Water Vapour Transmission of Materials*, which is specifically designed for single-ply sheets of materials, such as HDPE, low-density polyethylene, PVC, and other membranes.

Permeance is distinct from permeability. The vapour transmission rate of a material is referred to as its "permeability," typically stated in perm-inches; this number does not depend on the material's thickness. Instead, its "permeance" depends on thickness, much like the R-value in heat transmission. The permeability of a material divided by its thickness produces the material's permeance in perms. Permeance should be used to compare various membrane products with their vapour transmission resistance. The lower the permeance, the less vapour will come through the membrane.

Any material with a perm rating of less than or equal to 1.0 is commonly considered a vapour retarder. A true vapour-proof barrier would have a perm rating of 0.0; however, for practical purposes, the membrane industry often considers any material with a perm rating of 0.1 perm, and sometimes 0.01 perm for specific applications that are extremely sensitive to vapour transmission, to be a vapour-proof barrier.

The American Concrete Institute (ACI) defines a vapour retarder as having a permeance of less than 0.3 perm, as determined by ASTM E96. Further, ACI indicates that any material proposed for use as a vapour retarder or barrier should comply with ASTM E1745-09, *Standard Specification for Plastic Water Vapour Retarders Used in Contact with Soil or Granular Fill under Concrete Slabs*, and have a thickness of not less than 10 mils (0.25 mm).

ASTM E1745-09 defines three performance classifications (Classes "A," "B," and "C"), depending upon building requirements and installation demands. The minimum requirements under Class "A" serve to qualify and specify a resilient and effective underslab retarder or barrier for highly demanding installations and performance expectations. Class "B" and "C" rated products are intended for less demanding applications requiring less strength and puncture resistance. At a minimum, underslab gas barriers

(including any vapour-proof barrier used for the VI RMMs proposed herein) should meet or exceed the following Class "A" permeance, strength, and puncture requirements as vapour retarders or barriers per ASTM E1745-09 (also see ASTM E2121-12, *Standard Practice for Installing Radon Mitigation Systems in Existing Low-Rise Residential Buildings*):

- Permeance of 0.1 or less (as determined by ASTM E96/E96M-10 and ASTM E154-08a)
- Tensile strength of 7.9 kilonewton per metre (45 pound-force per inch) or better (as determined by ASTM E154-08a)
- Puncture resistance of 2,200 grams (5 pounds) or better (as determined by ASTM D1079)

ASTM E1745-09 does not specify a minimum material thickness.

I.2.2.2 Conceptual Design

A vapour-proof barrier will be installed over the venting system specified in Section I.2.1. At a minimum, the underslab gas barrier (vapour-proof barrier used for the VI RMMs proposed herein) should meet or exceed the ASTM E1745-09 Class "A" requirements; and have a minimum thickness of 15 mils (0.38 mm). The designer of the vapour barrier must also consider that the choice of membrane is appropriate for its intended application and will be chemically resistant to the specific COCs at their concentrations at the RA Property including residual NAPL. Although it is a requirement that NAPL will be removed within the area presented in Figure 7-2 before subsurface structures are permitted, residual concentrations of PHCs in the soil may remain. Slab-on-grade buildings are permitted in the NAPL area (Figure 7-2) and the barrier material selection must also consider resistance to hydrocarbon impacted vapours that may be present due to residual NAPL.

The membrane should be installed with an overlying sand or suitably graded crushed stone layer to prevent damage to the venting and barrier system components; particularly, the immediately underlying vapour-proof membrane. The barrier should be a sealed, continuous geomembrane with seamed and welded joints, as applicable to the material used. Alternatively, the barrier can consist of a cold-spray, fluid-applied, vapour-proof barrier material that will bond directly to a suitable geotextile, or to a new concrete surface.

Figure I-7 conceptually illustrates the installation of a vapour-proof barrier below a foundation slab as part of new construction. If a spray-applied membrane is installed, an appropriate protective base geotextile should be placed on the surface before application of the cold-spray, vapour-proof barrier material. In addition, a protective material should be applied over the cold-spray, vapour-proof barrier after application to provide durability and avoid damage during slab construction.

I.2.3 Sealing

For all new structures with foundations extending beneath the water table, waterproof and vapour-proof sealing of the interior of the foundation slab is a critical component of the VI RMM. Foundation joints or cracks may be sealed with a spray-on, vapour-proof-barrier material; urethane-based caulking; or expanding foam, depending on the need and application. Foundation penetrations, such as utility runs, floor drains, joints between slabs, or structural cracks in the foundation, will require sealing. The size and nature of the penetration or crack will dictate the sealing material and approach selected. As illustrated on Figure I-8, utility and pipe penetrations will be sealed using non-solvent-welded geomembrane boots in the case of HDPE-type liners, or sealing tape (or mastic) and lapping procedures for the thinner polyethylene and polyolefin vapour barriers.

I.2.4 Equivalency

Design concepts presented are conceptual. Other building-specific designs that meet the intent of the designs presented herein and achieve equivalent objectives, as determined by an appropriately skilled and qualified individual (such as a Professional Engineer registered in the Province of Ontario), can be used.

I.2.5 Quality Assurance and Quality Control Plan

In addition to specifying the adequate membrane thickness, strength requirements, puncture resistance, and permeance for the vapour-proof barrier related to its intended application, a quality assurance (QA) and quality control (QC) plan for the installation of the vapour barrier should be established. A QA/QC plan will mitigate the potential for defects that may arise from improper installation, as well as damage to the membrane that may arise during installation, subsequent concrete pours, and general construction activities. Protocols for addressing installation defects and membrane damage should also be developed and included in the QA/QC plans and installation and construction specifications, where appropriate. The QA/QC plans and specifications should include the following:

- Thorough inspection of liner seals along all edges and at penetrations
- Detailed examination for liner holes and tears
- Observations during subsequent concrete pouring or soil and granular filling
- Detailed procedures for testing the efficacy of the vapour-proof barrier upon its installation and after the slab is placed (for example, vacuum tests, pressure tests, smoke tests, and postconstruction indoor air tests)

Where damage or defects are identified, appropriate repairs should be undertaken and the associated inspection and testing procedures repeated to verify that the repair was completed in a satisfactory manner. The QA/QC plan and installation and construction specifications must be developed once site-specific project requirements are known. The manufacture of the membrane typically has a QA manual that specifies installation procedures.

I.2.6 Summary

The conceptual engineered systems for managing exposure risk associated with impacted soils and soil vapour within the RA Property will require additional detailed design elements as specific uses and designs for the RA Property are developed. The conceptual designs presented herein have considered constructability issues, as well as long-term issues, and should be readily applicable to detailed designs for the planned redevelopment.

Meeting Minutes

Subject **200 Beverley Street, Community Meeting, Tuesday, January 23, 2018**

Speaker: Glenn Pothier, think^{x} – Independent facilitator

Introductions:

- Scott Stewart: Deputy Chief Administrative Officer Infrastructure Development Enterprise, City of Guelph
- Martin Jewitt: Project Manager of Business Development, City of Guelph
- Terry Gayman: Manager of Development Environmental Engineering, City of Guelph
- Amer Obeidi: ARQi R&D Inc.

1. Senior City Officials

Speaker: Councilor Bob Bell (Ward 1)

Introduces, and mentions upcoming/ongoing Brownfield projects (Arthur Street, Gilmore St, upcoming Public meeting for Huron Street on Feb 12th)

IMICO – Why has it taken so long? Site has had a negative property value. Goal is to create a positive property value for developer to come in and make use of the Site. To move forward will need (1) public support; (2) support of rest of city councilor (continued funding); (3) federal/provincial government support to enable clean up to happen

Speaker: Councilor Dan Gibson (Ward 1)

2 years and $2.3 million allocated

2. City Objectives and Commitment

Speaker: Scott Stewart

- Represent Infrastructure development
- Objective is mixed use, priority for city council
- Money is spent on Brownfield clean up – one of 6 site requested funding from government
- MOU – includes future activities with Habitat for Humanity

Q&A – for councilors/city officials – No questions

3. Update on the Environmental Status/Conditions and Next Steps

Speaker: Terry Gayman

Introduces:

- Prasoon Adhikari (Environmental Engineer with City of Guelph)

- CH2M, Environmental Consultant with many Brownfield Projects; to file RSC, mandatory for mixed use redevelopment
- Introduce Ed Taves

Speaker: Ed Taves

Presentation

Discussion points outside presentation:

- Remediation: means getting concentrations down to MOECC guidelines
- Managed: leaving contamination on Site
- Anticipate some contaminants will be managed on site based on IMICO results to date
- Site Remediation: scope not known at this time, need to finish before speaking to site remediation

Q&A – Environmental

1. Can we have an example of how contaminants would be managed onsite:

   CH2M (Ed): Identified Risk Management Measure – prevents a contaminant from having an effect on environment; for example, if the parameter of concern is an issue for plants; a site gets paved and prevents plant growth

2. Corner of Alice and Stevenson, there is a little business with pipes– do they have anything to do with the IMICO cleanup

   City (Prasoon) answers– privately owned site, private remediation

   Owner of site (in crowd) answers further – owned for 20 years; main contaminant is toluene – site monitoring has been occurring from before he owned it. They have "put bugs down there", some chemicals, only remaining contamination is a small corner which is "not going anywhere". BP (British Petroleum) – bought Foseco and paying for ongoing environmental work.

3. With reference to the contaminant figures, they show a significant amount of the site is impacted. How much of the 13 acres is developable?

   CH2M (Ed): All of it is developable, just a matter of managing contaminants. Under the current regulatory regime, many industrial properties are fully developable.

4. With respect to the discussion on the difference between clean and managed – will the decision for what is to be cleaned up and what is to be managed depend on the development plan?

   CH2M (Ed): Yes. The decisions will depend on cost considerations if things start getting expensive. On site contaminant management versus clean-up will be rationalized with the development plan.

5. What happens at the edge of the property (with respect to delineation)?

   CH2M (Ed): Project ends at the property boundary.

6. If a chemical gets into the groundwater, does it move throughout the city?

   CH2M (Ed): Contaminants do move with groundwater; however, many mechanisms come into play. As it moves with the groundwater the concentration is reduced through dilution, contaminant movement is retarded through soil adsorption, precipitation of metals, biodegradation of organics. Depending on

the original amount of contaminants, these is always a time/distance when contaminant migration with groundwater essentially stops.

7. When dealing with zinc and managing in place, does it then have the potential to move to groundwater? How do you ensure the contaminants in place don't affect the groundwater?

   CH2M (Ed): Yes any contaminant left on site has the potential to migrate, but the groundwater quality has to be protected as part of any remedial solution. The current groundwater quality is being investigated and the end remediation plan will have to ensure that the groundwater quality is acceptable, including any long-term considerations. Risk management measures are often required to protect the groundwater; as an example, you change characterization of the site. Soil caps change the amount of infiltration from such things as rain water.

8. With respect to the mechanisms for managing on site – with the COCs we've seen, is there more natural treatment methods?

   CH2M (Ed): Yes, phytoremediation, bio treatments – usually these involve long term monitoring; generally for short term development they are not preferred due to timelines.

9. Does IMICO compare to other projects worked on, and timelines?

   CH2M (Ed): The Site is not exceptional, from our perspective, by end of year we should be looking at options for remediation.

4. ARQi /Planning and Team Introductions (7:55)

Speaker: Amer

- Not a mandatory process, lives here and is part of the community
- Interest in cutting edge technology on remediating site
- Micro retail
- Introduces team: Urban Strategies – Tim Smith, Emily Wall
- Masri O Architects – Reema Masri (based in Waterloo)
- Steve Howard, Chief Executive Officer, Habitat for Humanity, Wellington Dufferin Guelph
- Urban village, destination for the community

Speaker: Tim Smith, introducing Urban Strategies – worked on many Brownfields, mixed use community

- Sterling Road Redevelopment Toronto – planned light industrial and residential
- Planning Process: Spring 2018 for Open house #2 (Concept Development to share initial ideas for Site); Summer/Fall 2018 Open house #3 (Urban Design Master Plan)
- Goal: green city building.

5. Draft Development Principles

Speaker: Tim Smith

- What is important to achieve on the Site
- 1. Green – 2. Resource-Efficient 3. Mixed-Use (live work and visit) 4. Social inclusivity (mixed housing/incomes 5. Incubate creators and makers 6. Public Open Space 7. Community Amenities 8.

Pedestrian Friendly 9. Transitions – PDI facility on north end of rail tracks; south side empty buildings 10. Design excellence.

6. Roundtable Discussions

Other Guelph projects

York Road Parkland
Metal works –

Comment from Alice Street Resident: – Hwy 7 to downtown – vehicles cross Elizabeth and MacDonnell

- Opening a street have third artery to reduce traffic on Elizabeth
- Tim responds master plan will to have bigger picture in mind, Guelph junction railway will be part of discussions going forward

7. Next Steps & Closing Remarks

Speaker: Tim Smith

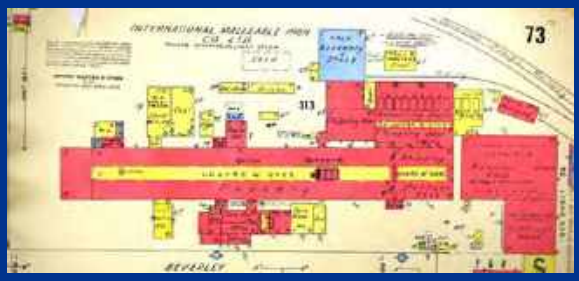
- Environmental will be on City's website; urban strategies may not be available.
- Will work with city to get 200 Beverley site up to date; dedicated website will be available in near future by ARQi
- Develop Preliminary Concepts
- Consult with Community Liaison Committee and City Staff
- Refine Preferred Concept
- Open House #2

Closing Remarks (9 pm) from Councilor Gibson: stay engaged, community

Former International Malleable Iron Company (IMICO)

200 Beverley Street, Guelph, Ontario

Environmental Site Assessment



Prepared for City of Guelph
January 23, 2018

JACOBS ch2m

Presentation Outline

1. Site Overview
2. Environmental Site Assessment (ESA) / Remediation Process
3. Phase One ESA
4. Phase Two ESA
5. Next Steps
6. Schedule
7. Questions/Discussion

Site Overview

- 5.2 hectares/12.8 acres in size
- First developed for industrial purposes in 1913 by IMICO, as a iron-jobbing foundry
- Over 40 buildings/areas with various operations: plating, galvanizing, annealing rooms, machine shop, etc.
- Foundry closed in 1989, generally vacant since that time
- 1989 to 1997 various non-industrial occupants, 1997 to present – City of Guelph
- All buildings have been demolished
- Interest to redevelop for mixed uses; residential/ parkland/ commercial
- Environmental conditions need to be investigated and managed

3

Environmental Site Assessment (ESA) / Remediation Process

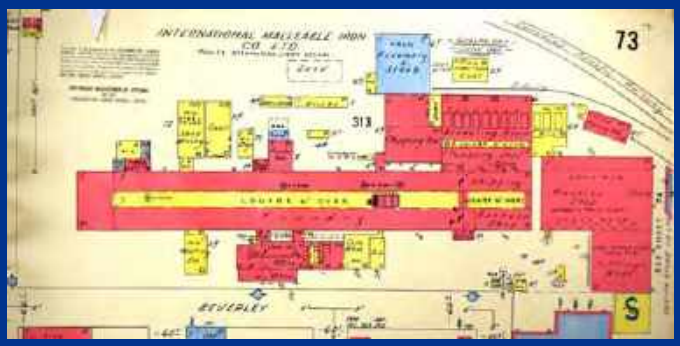
- Phase One ESA
  - Review of historical operations to identify potential contamination
- Phase Two ESA
  - Verify presence or absence of contamination, if present delineate extent of contamination
- Remedial Option Analysis (Cost Considerations)
  - remove contamination (Remediation)
  - manage the contamination (Risk Assessment, Risk Management Measures)
- Complete Site Remediation, Risk Assessment
- Complete Documentation, Regulatory Review Process

4

Phase One ESA

Terms

- Potentially Contaminating Activity (PCA)
- Area of Potential Environmental Concern (APEC)
- Contaminants of Concern (COCs)

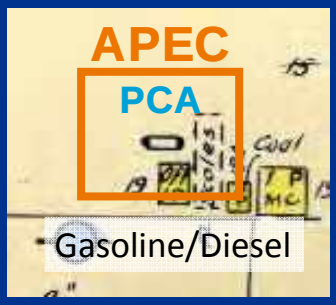


5

Phase One ESA

Terms

- Potentially Contaminating Activity (PCA)
- Area of Potential Environmental Concern (APEC)
- Contaminants of Concern (COCs)

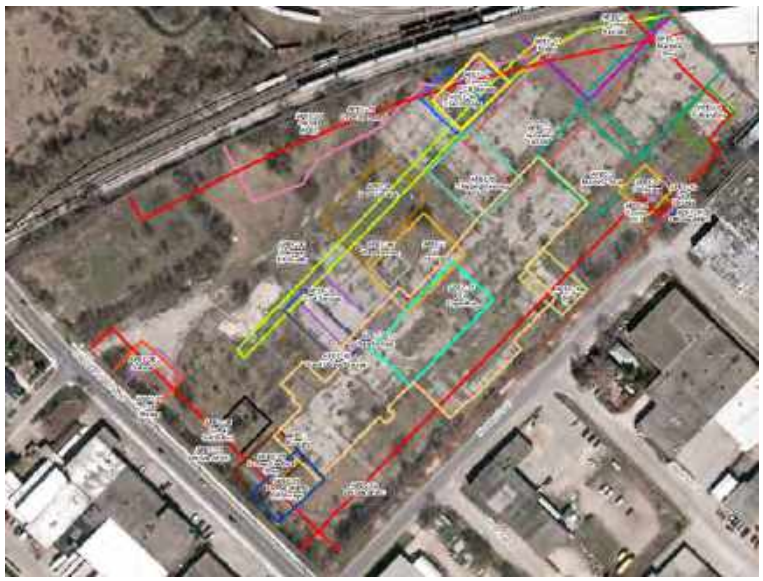


PCA	APEC	COCs
Operation of Underground Storage Tank	Soil and Groundwater around Tank	Gasoline/Diesel

IMICO - Phase One ESA has been completed

- 33 APECs, examples
  - Underground Storage Tank
  - Oil House
  - Plating, Galvanizing
  - Railway spur lines
  - Adjacent (off-Site) operations
  - and others

Contaminants of Concern (COCs)
- Metals (zinc)
- Petroleum hydrocarbons (PHCs)
- Solvent (trichloroethylene)
- PCBs
- PAHs (from coal, diesel, combustion byproducts)
- Salt(s)



7

Phase Two ESA

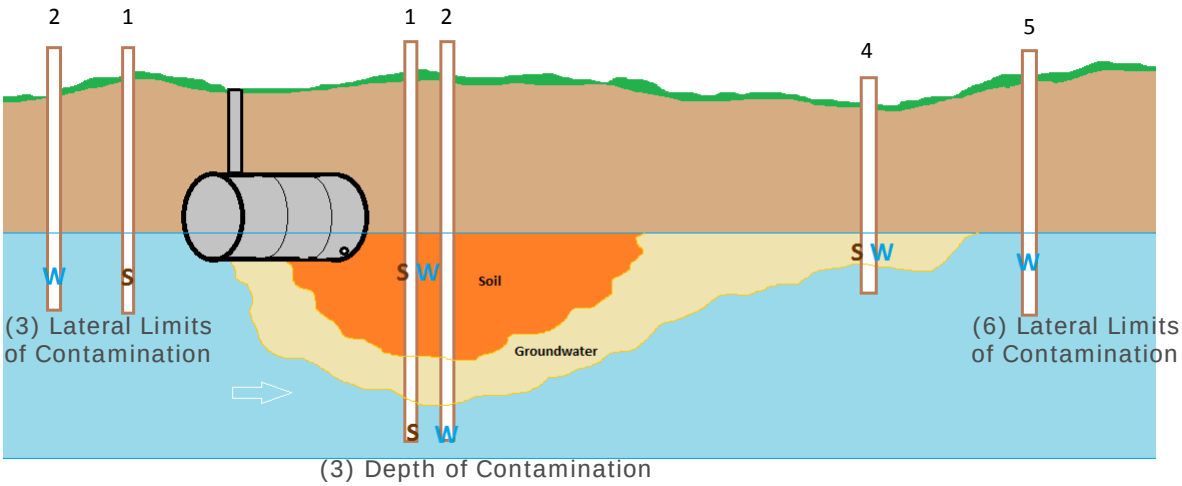
- Verify presence or absence of contamination
  - dig test pits, drill boreholes, construct groundwater monitoring wells
  - sample soil and groundwater
  - chemical analysis
- If contamination identified, delineate extent
  - depth and lateral extent of contamination

8

Previous Investigations and Reports

- 1989/1991 Environmental Investigation, Proctor & Redfern
- 1999 Supplemental Hydrogeologic Investigation Gartner Lee
- 1999 Demolition and Waste Removal Report Earth Tech
- 2004 Contaminant Investigation, Gartner Lee
- 2007 Phase I/II ESA Decommissioning Consulting Services (DCS)
- 2008 Preliminary Remedial Action Plan, DCS
- 2010 to 2016 Annual Groundwater Monitoring AECOM
- 2014 Phase One/Two ESA DCS
- 2016 Vertical Delineation of Chlorinated Volatile Organic Compounds (VOCs) WSP Canada

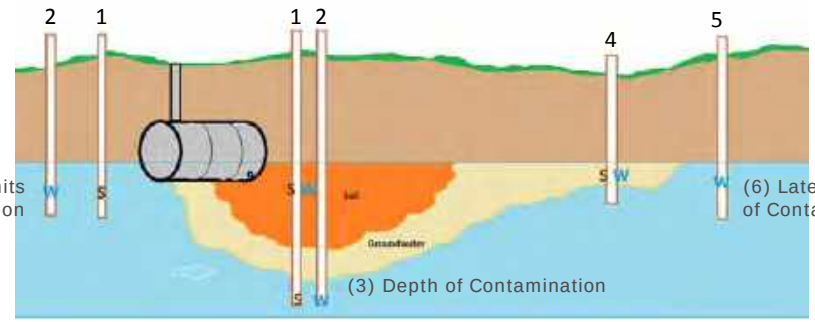
Phase Two ESA



IMICO – Status of Phase Two ESA

For most contaminants in soil Depth and Lateral Limits of Contamination have been established (3 and 6), but a few chemical compounds still need complete delineation

For groundwater, again most limits of contamination have been identified, but considerable effort still needed to define depth for some contaminants.



11

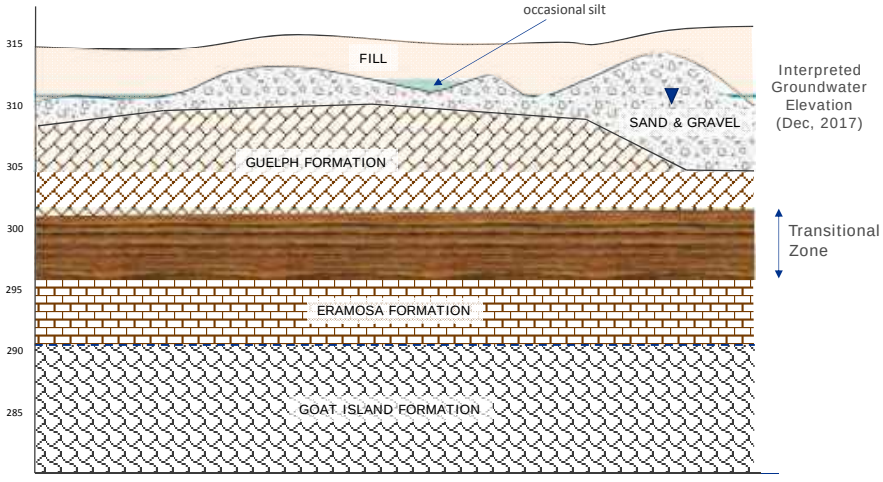
Phase Two ESA – Conceptual Site Model

Geology and hydrogeology

- Overburden Soil
  - Fill
  - Sand and Gravel
- Groundwater - generally occurs at the bottom of the overburden soil, where bedrock starts
- Bedrock, limestone, dolostone
  - Guelph Formation

    Hanlon, Wellington Member
  - Eramosa Formation

    Stone Road, Reformatory Quarry, Vinemount Member
  - Goat Island Formation



12

Phase Two ESA – Groundwater Flow Direction

Shallow Groundwater flow generally to the south/ southwest

13

Phase Two ESA – Investigation Locations/Results Metals in Soil

- Metal and inorganic exceedances widespread, zinc most common exceedance

14

Phase Two ESA – Investigation Locations/Results
Metals in Groundwater

- Metal and inorganic exceedances localized, zinc most common exceedance

15

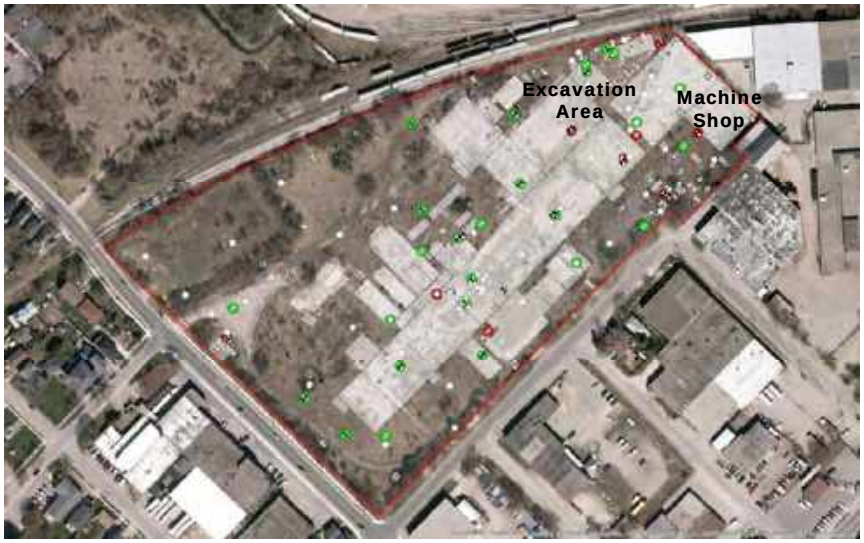
Phase Two ESA – Investigation Locations/Results
Volatile Organic Compounds in Groundwater

- Trichloroethylene and other chlorinated degradation products found on eastern portion of the Site in deeper bedrock
- Low exceedances in other areas of the Site

16

Phase Two ESA – Investigation Locations/Results
Petroleum Hydrocarbons in Soil

- Petroleum hydrocarbon (PHC) exceedances in several localized areas
- Free phase oil and high concentrations of PHCs observed in the area of the machine shop and excavation area



17

Phase Two ESA – Investigation Locations/Results
Petroleum Hydrocarbons in Groundwater

- Petroleum hydrocarbon (PHC) exceedances in the area of the machine shop and excavation area, corresponding to soil impacted areas. Some free phase oil in this area
- Localized impact in former foundry building

18

Summary thoughts

- Dirty versus Contaminated
- Remediated versus Clean

What does Clean mean - Remediated and/or Managed

Technical, regulatory processes are available to manage environmental conditions on the IMICO site. Remediation will likely include Risk Assessment. Development will likely need to incorporate Risk Management Measures.

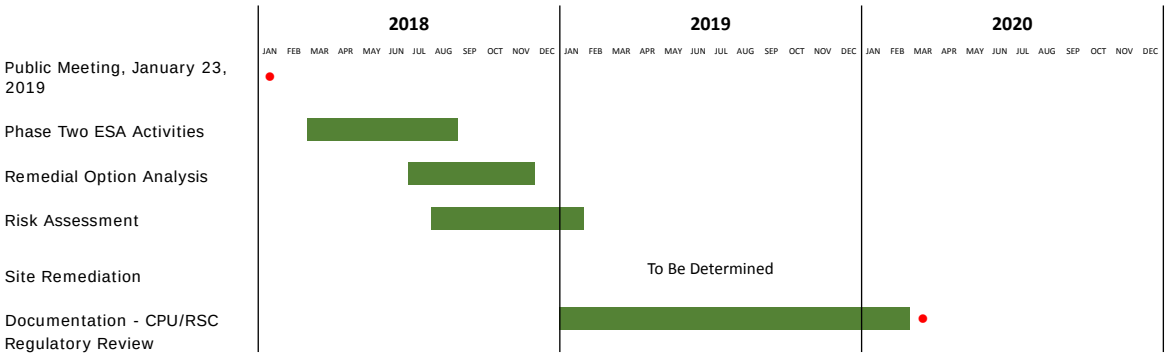
19

Next Steps

- Complete Phase Two ESA, depth and lateral delineation of contaminants in soil and groundwater } Underway
- Remedial Option Analysis (Cost Considerations)
  - remove contamination (Remediation)
  - manage the contamination (Risk Assessment, Risk Management Measures)
- Complete Site Remediation, Risk Assessment
- Complete Documentation, Regulatory Review Process

20

Schedule / Next Steps



21

Questions/Discussion

Thank You

Appendix J2
Response to Additional Public Comments Submitted to the City – March 2021

APPENDIX J2

Response to Public Comments on the November 2020 RA for 200 Beverley Street, Guelph, Ontario

Public Comments		Jacobs Response	Addressed Via
Risk Assessment			
Comments have been briefly described below for brevity. Please refer to the enclosed annotated version of the Intrinsik report entitled *Summary Memo of a Risk Assessment for the Property at 200 Beverley Street in Guelph, Ontario*, dated March 9, 2021 for full comments.			
RA1	PSF - Screening table does not show OTRs	Table F1-1 of the November 2020 RA provided both the applicable SCS and any alternate screening values, such as OTRs. The current RA has been revised to address the MECP comments on the screening process.	November 2020 RA O. Reg. 153/04 MECP Regulatory RA Review Process
RA2	PSF - HH CSM does not call out potable water pathway	Figure 4-1 of the November 2020 RA provided clarification on the potable drinking water pathway. Footnote f states: As groundwater at the Site is potable, the ingestion of groundwater pathway includes both incidental ingestion (as a result of subsurface activities) and ingestion of water from the municipal water supply.	November 2020 RA O. Reg. 153/04 MECP Regulatory RA Review Process
RA3	Discrepancy in groundwater flow direction between Section 3 and Section 4.4.6	The groundwater flow direction wording in Section 4.4.6 was revised to be consistent with the Phase Two CSM, that is: "…the predominant groundwater flow direction in the Overburden and Bedrock Contact Zone is from the northeast to the southwest, with localized flow from west to east on western portion of the Site and localized flow from east to west on the eastern portion of the Site. Groundwater in the Eramosa Formation (Potentiometric surface), appears to flow predominantly to the east."	May 2020 RA
RA4	Use of half MDLs in B(a)PE calculation vs. Intrinsik approach of using full MDL value	Use of Half MDLs in B(a)PE Calculation – The half MDL method is inferred from the MECP's approach outlined in the 2011 document entitled *Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act* (Analytical Protocols). Section 3.1.1.4 (Dibenzo-p-Dioxins/Dibenzofurans [Dioxins/Furans, PCDDs/PCDFs]) of the Analytical Protocols outlines the MECP's approach for calculating the TEQ for dioxins and furans, which substitutes half MDLs for nondetect results. As the dioxins and furans TEQ and B(a)PE calculations are essentially analogous, the approach employed in the RA is considered appropriate.	O. Reg. 153/04 MECP Regulatory RA Review Process
RA5	Use of only the S1 component value in secondary screening vs. Intrinsik approach of also using S2 and S3 component values	Since the most sensitive future use of the Site is residential, the most conservative MECP component value (S1) was selected as the secondary screening value for soil. This approach was taken to simplify the exposure and risk calculations. That is, so a common set of COCs was carried forward for all human receptors onsite, including residents, workers, and subsurface workers. The approach is different than that employed by Intrinsik, but achieves the same result (that is, exposure and risk to the onsite receptors are either qualitatively or quantitatively assessed).	O. Reg. 153/04 MECP Regulatory RA Review Process
RA6	Secondary screening using S-GW1 and GW1-Odour	Acknowledged. These pathways are considered minor in relation to the pathways for groundwater which were assessed quantitatively. For completeness, the following has been added to the May 2020 RA: • A qualitative assessment of groundwater odour has been added as Section 4.4.3.10. Since this pathway is based on aesthetic criteria and is not health-based, no RMMs above and beyond what is currently outlined in the RMP (Section 7) have been proposed in relation to this pathway. • A qualitative assessment of soil leaching to potable groundwater has been added as Section 4.4.3.11. No additional RMMs above and beyond what is current outline in the RMP (Section 7) have been proposed in relation to this pathway.	May 2020 RA O. Reg. 153/04 MECP Regulatory RA Review Process
RA7	Screening using component values derived in the MGRA using updated TRVs	Acknowledged. Jacobs agrees that this method of screening has become more commonplace in recent months. On other projects, Jacobs has noted that the MECP has typically commented that this "updated" method of screening be used on new RAs when reviewing the PSF, but has not made the same comment on RAs that are already drafted (which appears to be the case for the 200 Beverley Street RA). Using either method, all COCs identified at the Site are either qualitatively or quantitatively assessed in the RA; therefore, slight differences in the screening values used for a subset of the COCs is unlikely to result in a material change to the results or conclusion of the RA, nor the proposed RMMs.	O. Reg. 153/04 MECP Regulatory RA Review Process
RA8	Showing Offsite Residents on HH CSM	Section 4.2.1 of the November 2020 RA includes Residents under the umbrella of "Offsite Surface Receptors". Residents were inadvertently omitted from the same list in Footnote b on Figure 4-1 and 4-2 (HH CSM). The current RA has been revised to address this omission.	May 2020 RA O. Reg. 153/04 MECP Regulatory RA Review Process
RA9	TRV selection	Acknowledged. Any TRV not endorsed by the MECP, but utilized in the RA have been identified in Table 4-26. For these TRVs, a corresponding toxicity profile has been provided in Appendix H.	O. Reg. 153/04 MECP Regulatory RA Review Process
RA10	Use of an HQ of 0.5 for TCE for inhalation only	Acknowledged. Section 4.4.1 of the RA provides a rationale for the choice of inhalation HQ for TCE, which Jacobs considers to be reasonable and adequately protective of human health given that groundwater on the Site is not and will not be used as a potable resource.	O. Reg. 153/04 MECP Regulatory RA Review Process

Public Comments		Jacobs Response	Addressed Via
RA11	Offsite ingestion of groundwater for subsurface workers and potable groundwater	Acknowledged. A comprehensive GMP has been developed as part of the RMP (Section 7.4.3.1) for the RA Property and will form a requirement of the CPU. As shown in Tables 7-9 and 7-10 both these offsite pathways have been considered in the development of the GMP. The data collected through the GMP will establish groundwater quality trends at select monitoring wells through a minimum of quarterly monitoring (Year 1) and semi-annual monitoring (Year 2). The CPU binds the Property Owner to specific actions depending on the results of the GMP, in consultation with the MECP District Office. The MECP Abatement Process specifically deals with addressing offsite risks.	O. Reg. 153/04 CPU Regulatory Process MECP Abatement Process
RA12	Remedial actions not listed as contingencies in RMP	The remedial actions listed in the comment were indeed listed in the RMP. Section 7.4.3.1 (page 7-19) of the November 2020 RA states: *The remediation measures, if required, will be designed by a P.Eng. and may include in situ chemical or biological treatment, installation of a passive NAPL collection system, hydrogeological or reactive barrier wall, vapour cut-off trench, or altering groundwater flow patterns using a pump-and-treat system.*	O. Reg. 153/04 CPU Regulatory Process MECP Abatement Process
RA13	Why conduct ongoing groundwater monitoring	As described in the response to Comment RA11, the data collected through the GMP will establish groundwater quality trends at select monitoring wells through a minimum of quarterly monitoring (Year 1) and semi-annual monitoring (Year 2). The GMP has merit because it will allow decisions to be made based on the evaluation of more recent groundwater data collected at a higher frequency of sampling than has been collected to date (via the staged Phase Two ESA investigations). The CPU binds the Property Owner to specific actions depending on the results of the GMP, in consultation with the MECP District Office. The MECP Abatement Process specifically deals with addressing offsite risks. Section 7.4.3 describes the potential "actions" that may arise via the CPU and Abatement Process based on the results of the GMP including: • Further investigation or assessment including modelling or fate and transport assessments • Removal of NAPL to characterize and assess persistence and volume • Installation of additional monitoring wells or soil vapour probes • Completion of a remedial option feasibility study, remedial action plan, or both • Assessing and implementing remedial technology options to prevent such offsite migration; or • Some combination of these The March 18, 2021 MECP Schedule A comments on the RA specifically state: "Any assessment of risk or development of property specific standards in the RA that may be intended to apply to off-site properties are beyond the scope of a RA under the Regulation and accordingly are not part of the Ministry's review." Therefore, the evaluation of risk for offsite receptors is beyond the scope of the RA. Offsite risks will be addressed in the future via the requirements of the CPU and the MECP Abatement Process, if necessary.	O. Reg. 153/04 CPU Regulatory Process MECP Abatement Process
RA14	Public Communication only done because Wider Area of Abatement was expected	The requirement for Public Communication for the overall project was stipulated in the 2017 Request for Proposals. Public communication is a key aspect of the City's planning process to guide decisions regarding the future redevelopment of the Site. Updates regarding the environmental condition of the property and status of the Phase One and Two ESA investigations constituted a portion of the overall Public Communication Plan carried out by the City and their partners. Therefore, the Public Communication Plan was not executed with O. Reg. 153/04 processes in mind, but rather as part of the City's planning process to foster community engagement. The decision to declare a Site with a Wider Area of Abatement designation is at the discretion of the MECP District Engineer.	City Planning Process O. Reg. 153/04 MECP Regulatory RA Review Process

Notes:

B(a)PE = benzo(a)pyrene equivalence

CONFIDENTIAL

Dear Mr. Mauro:

RE: Summary Memo of a Risk Assessment for the Property at 200 Beverley Street in Guelph, Ontario

Intrinsik Corp. (Intrinsik) is pleased to submit the following summary memo addressing the request for a review of the Risk Assessment (RA) and supporting Record of Site Condition (RSC) information submitted to the Ministry of the Environment, Conservation and Parks (MECP) by CH2M/Jacobs for the property located at 200 Beverley Street (hereafter referred to as the "Site").

The memo focuses on the key conclusions from the RA and supporting RSC information and identifies technical deficiencies, as per the requirements of Ontario Regulation 153/04 (O. Reg. 153/04) and best scientific practices. This memo assumes that the underlying data presented in the Phase Two CSM documentation and/or related reports has properly characterized identified areas of potential environmental concern (APECs) on the Site. As such, Intrinsik has not reviewed the data for the purposes of determining if appropriate characterization has been completed on Site. The proposed Risk Management Measures (RMMs) outlined in the revised November 2020 RA have blocked most of the relevant possible exposure pathways at the Site based on existing concentrations and as such any potential changes in the maximum concentrations arising from future environmental assessment or delineation work are not anticipated to alter the RA conclusions or RMM recommendations.

Ultimately the primary concern we have with the RA, its conclusions, and the resulting Risk Management Plan (RMP) is how it has managed (or not managed, as the case appears to be) the potential for off-site migration of contamination in groundwater. Contaminated groundwater is leaving the RA property and flowing onto the neighbouring downstream 10 Kingsmill Avenue property. It is important to consider offsite migration of contaminated groundwater because there may be a potential for risks to off-site human receptors that are not being protected by the RMMs planned for the 200 Beverley Street property. Rather than identifying the requirement of a remediation option such as a permeable reactive barrier, the RMP provides contingency measures for offsite groundwater movement or NAPL observations. As discussed in this memo, the data illustrates exceedances at sentinel monitoring wells located in the northeast corner of the Site, and taken with the RWDI investigations, there is contaminated groundwater flowing onto the downstream property at 10 Kingsmill Avenue.

This memo provides a short discussion of the Site background, Intrinsik's comments on the Pre-Submission Form (PSF) and revised RA, a discussion on off-site migration of contaminants of concern (COCs) in groundwater to 10 Kingsmill Avenue, and a final conclusion section. Short summaries of the Phase One ESA, PSF submission and the revised RA are provided in Attachment 1 at the end of this document. The pertinent information for the RA review is presented in the PSF submission and revised RA are based on the findings of the Phase Two ESA. A summary of the Phase Two was not provided in this memo as the detailed review of the site investigations were completed by RWDI.

As part of this summary memo, Intrinsik staff reviewed the following seven (7) documents:

- CH2M (CH2M HILL Canada Limited). 2017. Draft Phase One Environmental Site Assessment - Former International Malleable Iron Company 200 Beverley Street, Guelph, Ontario. Prepared for City of Guelph. August 18, 2017.
- CH2M. 2019. Risk Assessment Pre-Submission Form 200 Beverley Street, Guelph, Ontario. Prepared for City of Guelph. February 2019.
- Appendix A2 Response to PSF Comments in Schedule A for 200 Beverly Street, Guelph, Ontario.
- Jacobs (Jacobs Engineering Group Inc.). 2020. Former International Malleable Iron Company – Draft Phase Two Environmental Site Assessment. Prepared for City of Guelph. June 12, 2020
- Jacobs. 2020. 200 Beverley Street, Guelph, Ontario Risk Assessment (Rev 0). Prepared for City of Guelph. June 2020.
- Appendix A3 Response to RA Comments in Schedule A for 200 Beverley Street, Guelph, Ontario
- Jacobs (Jacobs Engineering Group Inc.). 2020. 200 Beverley Street, Guelph, Ontario Risk Assessment (Rev 1). Prepared for City of Guelph. November 2020.
- RWDI. 2021. Review of Supporting Documentation – City of Guelph Record of Site Condition. 200 Beverley Street, Guelph, Ontario. Final Report. RWDI # 2102539. March 9, 2021.

Site Background

Based on our review of these documents, the following brief discussion presents background information for the Site. The Site was historically utilized for industrial/commercial purposes and was identified as the former International Malleable Iron Company (IMICO) foundry facility. To Intrinsik's understanding, with the exception of concrete foundations, the RA Site was vacant with no buildings or structures at the time of the site reconnaissance. The redevelopment plans are unknown but may include residential, parkland, and/or commercial use. Residential, commercial, and industrial properties are to the north and east of the Site. Beverley Street is to the south of the site and farther south are residential, commercial, and industrial properties. Stephenson Street South is to the west of the Site and farther west are residential and commercial properties. As such, off-site human receptors identified in the RA include residents, patrons, and workers at nearby homes, businesses, or facilities. The nearest surface water bodies are the Eramosa River located approximately 0.5 kilometres (km) south), and the Speed River approximately 1.1 km west. Based on the Phase Two CSM (Jacobs, 2020), groundwater flow in the overburden and bedrock contact zone is northeast to southwest and the flow in the Eramosa formation is to the east. The minimum depth to groundwater was identified as being 0.93 metres below ground surface (mbgs). Based on the site characteristics, the Table 6 Generic Site Condition Standards (SCS) for Shallow Soils in a Potable Groundwater Condition

for Residential/ Parkland/Institutional (RPI) Property Use in coarse soils were selected as the applicable SCS for the Site. Based on the screening conducted in the RA, thirty-eight (38) chemical parameters in soil and thirty (30) chemical parameters in groundwater were retained as COCs for the RA. It was also noted that non-standard delineation was used for cis-1,2-dichloroethylene (cis-1,2-DCE) in groundwater at OW31.

Intrinsik's Comments on the PSF and RA

Though Intrinsik and CH2M/Jacobs differ on some of the finer elements of the completed risk assessment, these are not expected to affect the conclusions of the assessment for the property itself. The RA appears to have been competently conducted with appropriate risk management measures established to address residual risk on the property itself. The following bullets identify notable differences from RA methodology typically employed by Intrinsik on similar O. Reg. 153/04 RA submissions:

RA1

- PSF (CH2M, 2019)
  - Appendix D - Screening for soil and groundwater chemical parameters was against Table 6 SCS and, for select chemicals, also against Ontario Typical Range (OTR) and provincial groundwater monitoring information system (PGMIS) values. However, the screening tables show values for the Table 6 SCS only. Additionally, there are several contaminants which do not have SCS or ORT values and have been identified as not having a standard available. It is acknowledged that the Ministry also commented on this screening approach and specifically about bismuth in their comments on the PSF and on the RA.

RA2

  - Appendix E
    - It is acknowledged that no existing drinking water wells were identified on the Site, however, the human health CSM should assess "ingestion of potable groundwater" as the site is a Table 6 site. The CSM identified "Ingestion (incidental) and dermal" as incomplete pathways which, based on the applicable SCS, is not representative of the Site.

- Revised RA (Jacobs, 2020)

RA3

  - Based on the Phase Two CSM shown in Section 3.2 of the RA, groundwater flow in overburden and bedrock contact zone is northeast to southwest. The flow in the Eramosa formation is east. However, the RA discussion in Section 4.4.6 (Interpretation of Off-Site Health Risks) identifies that groundwater in the overburden and bedrock contact zone generally flows from west to east on western portion of the Site and flows from east to west on the eastern portion of the Site. Groundwater in the Eramosa Formation (Potentiometric surface), appears to flow to the southeast. There is a discrepancy between the flow descriptions for the overburden and bedrock contact zone and it is recommended that groundwater flow be clearly described. From Intrinsik's review of the Jacobs and RWDI data, the groundwater flow is to the south or southeast.

RA4

  - For the calculation of benzo(a)pyrene equivalent (B(a)PE), half detection limits were used in the calculation for concentrations that were reported as non-detect. In Intrinsik's methodology, concentrations that are non-detected are not halved for this calculation.
  - Secondary screening was presented in Tables F1-3 through F1-5e. Screening was against the Table 2 S1, GW1, S-GW3, and GW3.

RA5	• Intrinsik's methodology includes screening against the S2 and S3 component values protective of the maintenance worker and construction worker via direct contact.
RA6	• As the potable water scenario is applicable to this site, secondary screening against S-GW1 and GW1-odur should also be completed.
RA7	• Updated TRVs are selected and endorsed by MECP. Intrinsik's methodology includes completing the secondary screening with the component values presented in the MGRA model (2016) with the updated MECP TRVs.
RA8	○ The Human Health CSM on pg. 279/3142: It is noted that there are off-site residential uses and as such, off-site residents would be a receptor also considered by Intrinsik.
RA9	○ In some instances, the TRVs selected in the RA differ from what Intrinsik would utilize. However, the Ministry allows for deviations from the Ministry endorsed values with property toxicological justification.
RA10	○ The RA identifies that a hazard quotient of 0.5 (for inhalation pathways only) for trichloroethylene is considered appropriate for the assessment. Intrinsik's methodology conservatively uses the hazard quotient of 0.2 for trichloroethylene for all pathways if the site is identified as a potable site.
RA11	○ Ingestion of groundwater: RA identified that "risks to offsite receptors (that is, offsite Construction and Utility Workers) were indirectly assessed through the modelling for onsite Construction and Utility Workers". The RA should discuss off-site migration of groundwater impacts for the potable water supply. As noted below, this is inappropriate as the on-site risks to construction and utility workers are addressed through the implementation of a health and safety plan (HASP) while no such HASP may be present for downstream neighbouring properties (like 10 Kingsmill Avenue) not bound by the requirements of the filed CPU for the Site.

Off-site Considerations

Based on the Interpretation of Off-Site Health Risks discussion, provided in Section 4.4.6 of the RA, of the thirty (30) COCs identified in groundwater, twenty-three (23) COCs were identified to potentially have off-site exceedances of their respective Table 6 RPI SCS. Chlorinated VOCs identified as COCs in groundwater (including trichloroethylene) were noted to have the potential to exceed Table 6 SCS off-site on the eastern portion of the site in the overburden and bedrock contact zone and Eramosa Formation where the groundwater appears to flow to the east. Additionally, there are PHC exceedances in groundwater, corresponding to soil impacts in the area of the machine shop and excavation area where there is residual free phase product.

Section 4.4.6 of the RA concludes that "the potential for an offsite exceedance of the applicable generic MECP standard for several parameters cannot be ruled out." Further, based on the RWDI analysis, there are confirmed off-site exceedances as a result of migration from the site. Based on our review of the data presented in the revised RA, we would agree with this conclusion. However, Jacobs addresses this possibility not by specifying mitigation actions to prevent or reduce COC flow off-site (such as a permeable reactive barrier [PRB] or similar remedial action) as we have observed used in other sites with similar groundwater plumes travelling off-site. Rather they state "[o]ffsite groundwater quality can be addressed onsite by monitoring groundwater movement, allowing natural attenuation, and notifying appropriate stakeholders in the event of offsite migration." A number of these COCs are recalcitrant chemicals that do not degrade readily or rapidly in the environment (*i.e.*, chlorinated volatile

organic compounds), and as such, natural attenuation should not be relied on to mitigate offsite risks to directly adjacent properties.

To further assess off-site health risks, based on the location of 10 Kingsmill Avenue in relation to the Site, the monitoring wells in the northeast corner of the Site were reviewed by Intrinsik for exceedances which may impact the 10 Kingsmill Avenue property. Table 1 below identifies the list of monitoring wells which were screened by Intrinsik. Figure 1 and 2 are provided to illustrate the location of the sentinel monitoring wells reviewed.

Table 1	**List of Sentinel Monitoring Wells Reviewed for Assessment of Potential Off-Site Exceedances from the Northeast Corner of the Site**
MW17-105S	OW24D
MW17-105D	OW24S
MW18-129D	MW18-134S
OW09-I	MW18-134D
OW09-II	OW13-39S
MW19-137S	OW13-39D
OW14	OW18-I
OW31	OW18-II

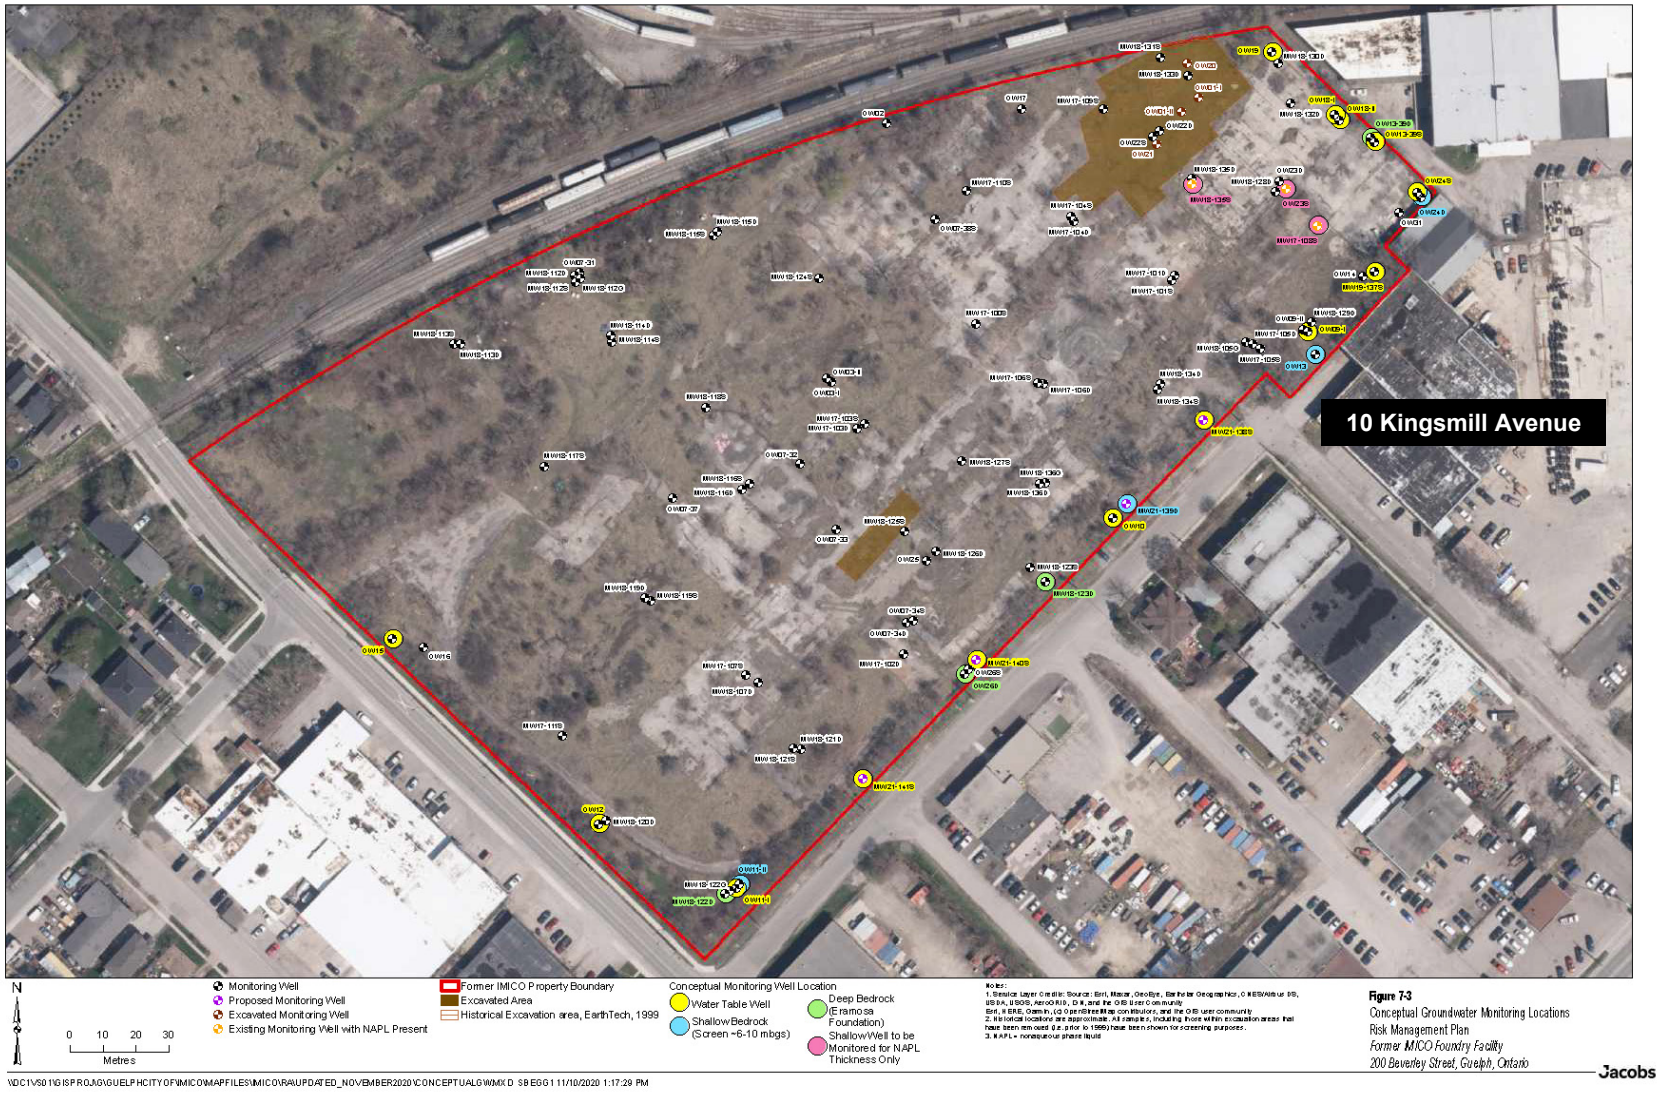

Figure 1 Groundwater Monitoring Locations presented in the Risk Management Plan

Figure 2 Locations of Sentinel Monitoring Wells (highlighted in orange) Reviewed for Assessment of Potential Off-Site Exceedances from the Northeast Corner of the Site

Based on the exceedances presented in the Phase Two CSM and RA, the following maximum concentrations in groundwater were identified as exceedances of the applicable on-site Table 6 RPI SCS at the monitoring wells identified in Table 1. Please note, the following table (Table 2) presented the Table 2 RPI SCS in addition to the Table 6 RPI SCS as off-site properties may potentially have deeper bedrock and as such the applicable off-site SCS may be the Table 2 SCS. Additionally, although the current land use for the 10 Kingsmill Ave property is industrial/commercial, the RPI SCS were conservatively utilized for this screening approach to account for potential future redevelopment.

Conclusions

As presented in Table 2 above, groundwater concentrations of a number of COCs (*e.g.*, benzene, ethylbenzene, PHC F1, 1,1-DCE, n-hexane, TCE and vinyl chloride) exceed the appropriate generic SCS at the closest sentinel wells on the property boundary with the 10 Kingsmill Avenue property (*e.g.*, MW18-134D, MW17-105S, OW13, MW17-105D, OW09-I, OW09-II, MW18-129D, MW19-137S, OW14, OW31, OW24S, and OW24D). Furthermore, the RA states that "[t]he proposed PSSs for groundwater COCs (presented in Table 4-39) could result in concentrations exceeding the applicable generic MECP standards (Table 6 SCS) at the nearest downgradient offsite property if groundwater containing COCs at PSS concentrations greater than the applicable SCS migrates offsite" (page 78 of revised RA report). As noted in the RA report, groundwater in the Eramosa Formation appears to flow to the east which would appear to be flowing to the 10 Kingsmill Avenue property. Further, as noted above, shallow groundwater from 200 Beverley Street is also flowing south and southeast towards the 10 Kingsmill Avenue property.

In our experience, sites which have significant groundwater contamination (particularly chlorinated VOCs) flowing onto downstream properties would require some form of remedial action to mitigate the flow, such as installation of PRBs, chemical injections and/or hydraulic

RA12 control by pump and treat. The highlighted options are often presented as measures to prevent offsite movement of contaminated groundwater. However, none of these were suggested in the current RA or RMP even as contingencies should off-site concerns be raised in the future.

RA13 Given concentrations at the sentinel wells at the property boundary already exceed the generic SCS and based on what is known from the RWDI data that there are already concentrations above the generic SCS, we are unsure what would be gained by ongoing groundwater monitoring. For example, if we consider the maximum concentration of TCE of 7,900ug/L at OW24D, we would be expecting potential risks to downgradient indoor workers through the inhalation pathway as the Table 6 GW2 industrial component value is 0.86ug/L. The concentrations onsite already require a significant amount of mitigation to prevent adverse human health risks, including vapour mitigation, potable water use prohibitions, basement prohibitions in areas of LNAPL, and HASPs to protect construction or trench workers. These can easily be enforced through ongoing requirements specified in a filed CPU for the RA property. However, there are no proposed protections or mitigation measures in the RA or RMP for stopping the migration onto 10 Kingsmill Avenue. We are unsure of what simply notifying appropriate stakeholders in the event of off-site migration (which appears to have already occurred and is still ongoing) will gain.

RA14 Additionally, we are surprised that the MECP District Engineer has not declared this Site (200 Beverley Street**)** a *Wider Area of Abatement* (WAA) designation. It is a high-profile site with significant contamination which has obviously migrated beyond the property boundaries. Intrinsik has conducted a number of risk assessments under O. Reg. 153/04 for much simpler and less contaminated sites across the Greater Toronto Area – some of which the contamination was from a flow-through condition – that the District Engineer designated as WAA. In fact, as part of Section 8 of the RA, a description of an optional communication plan was included. This is not typically required for any Tier 3 RA unless it is declared a WAA site. I suspect that Jacobs and their client expected it to be declared a WAA and had initiated this process in anticipation of the requirement potentially arising during the Ministry regulatory review process.

We hope this summary memo provides you and your client with the necessary information required for your purposes. If you have any questions regarding these comments, please do not hesitate to contact me at (905) 364-7800, ext. 206, or *via* email at gferguson@intrinsik.com. We thank you for the opportunity to complete this review.

Yours sincerely,
INTRINSIK CORP.

Attachment 1 - Document Summaries

The following section provides summaries of the Phase One ESA, PSF submission and the revised RA dated November 2020.

CH2M. 2017. Draft Phase One Environmental Site Assessment - Former International Malleable Iron Company 200 Beverley Street, Guelph, Ontario. Prepared for City of Guelph. August 18, 2017.

- At the time of the Phase One Environmental Site Assessment (ESA), the Site was vacant with concrete floor slabs of the demolished buildings. The site was historically used for industrial purposes and was identified as the former International Malleable Iron Company (IMICO) foundry facility.
- At the time of the Phase One ESA, adjacent property uses to the north, east, and south of the Site were residential, industrial, and commercial. Residential use was identified to the west of the Site.
- Thirty-three (33) areas of potential environmental concern (APEC) were identified, of which twenty-nine (29) were from on-site potentially contaminating activities (PCAs) and four (4) were from off-site PCAs.
- Contaminants of potential concern (COPCs) identified included metals and inorganics, VOCs, PHCs, PAHs, PCBs, ABNs and CPs. Free phase product was noted to be potentially exist on Site.
- The Site was identified to be redeveloped for residential/ parkland/ institutional land use purposes.
- The groundwater flow was anticipated to be south, toward Eramosa River located approximately 800m southeast of the site. Waterbodies within the Phase One Study area included a portion of the Hanlon Creek and Mill Creek Swamp located off site.
- Based on previous investigations, which were reviewed by CH2M, depth to bedrock was identified to be approximately 2.0 metres below ground surface (mbgs).

CH2M. 2019. Risk Assessment Pre-Submission Form 200 Beverley Street, Guelph, Ontario. Prepared for City of Guelph. February 2019.

- PSF identified the following:
    - Applicable SCS: Table 6 RPI SCS for coarse soils
        - Site intended for commercial, community, parkland, residential use.
        - pH value for surface soil was less than 5 and greater than 9. PSF identified that further investigation was needed to ensure this would not be a Table 1 Site. The PSF assumes the Table 6 SCS is applicable.
        - Potable site
        - Shallow bedrock (encountered < 2 mbgs)
    - Media sampled included: Soil and Groundwater.

- Identified depth of organic contamination in soil to be from 0-2.89m and inorganic contamination to be from 0-3.2m
- Three (3) groundwater units identified, and minimum depth to groundwater was 0.93 mbgs.
- Thirty-nine (39) centimeters of light non-aqueous phase liquid (LNAPL) was visually observed on site.

- Attachment A – Phase One and Two Summaries
  - The Phase Two ESA did not look at vapour intrusion. RA would need to be reviewed to ensure that future buildings be assessed for this exposure pathway.
  - The following tables present COCs in soil and in groundwater.

Table 6-7c. Contaminants of Concern Identified in Soil
200 Beverley Street, Guelph, Ontario

Soil Contaminants of Concern	
2-(1-)Methylnaphthalene	Fluorene
Acenaphthene	Indeno(1,2,3-Cd)Pyrene
Acenaphthylene	Lead
Anthracene	Mercury
Antimony	Molybdenum
Arsenic	Naphthalene
Benzene	Nickel
Benzo(a)anthracene	PCB, Total
Benzo(a)pyrene	Petroleum Hydrocarbons F2 (C10-C16)
Benzo(b)fluoranthene	Petroleum Hydrocarbons F3 (C16-C34)
Benzo(g,h,i)perylene	Petroleum Hydrocarbons F4 (C34-C50)
Benzo(k)fluoranthene	Phenanthrene
Cadmium	Pyrene
Chrysene	Thallium
Cobalt	Trichloroethylene
Copper	Vanadium
Dibenzo(a,h)anthracene	Xylenes, Total
Ethylbenzene	Zinc
Fluoranthene	

F = fraction
PCB = polychlorinated biphenyls

Table 6-10c. Contaminants of Concern Identified in Groundwater
200 Beverley Street, Guelph, Ontario

Groundwater Contaminants of Concern	
1,1,1-Trichloroethane	Fluoranthene
1,1-Dichloroethane	Lead
1,1-Dichloroethene	Naphthalene
2-(1-)Methylnaphthalene	n-Hexane
Acenaphthene	Petroleum Hydrocarbons F1 (C6-C10)
Anthracene	Petroleum Hydrocarbons F2 (C10-C16)
Arsenic	Petroleum Hydrocarbons F3 (C16-C34)
Benzene	Petroleum Hydrocarbons F4 (C34-C50)
Benzo(a)anthracene	Phenanthrene
Benzo(a)pyrene	Pyrene
Benzo(b&j)fluoranthene	Tetrachloroethene
Benzo(k)fluoranthene	trans-1,2-Dichloroethene
Chrysene	Trichloroethylene
cis-1,2-Dichloroethene	Vinyl Chloride
Ethylbenzene	Zinc

F = fraction

- Attachment C – Sampling & Analysis Plan

- Attachment D – Data relied on for the RA
    - Soil screening is completed against Table 6 SCS. The table also identifies screening against Ontario Typical Range (OTR) values for select chemical parameters.
    - Groundwater screening is completed against Table 6 SCS. The table also identifies screening against provincial groundwater monitoring information system (PGMIS) values for select chemical parameters.

- Attachment E – Human health and ecological conceptual site models (CSMs)

- Attachment F – Toxicity reference values

- Attachment G – Legal Property Information
    - Legal letter from City of Guelph and plan of survey

- Attachment H – Supporting Infromation includes
    - Discussion on species at risk
    - Certificate of compliance for CH2M
    - CVs of team

Jacobs (Jacobs Engineering Group Inc.). 2020. 200 Beverley Street, Guelph, Ontario Risk Assessment (Rev 1). Prepared for City of Guelph. November 2020.

- Non-standard delineation was used for cis-1,2-dichloroethylene (cis-1,2-DCE) in groundwater at OW31. Additional vertical delineation is not required as per the RA.

- Chemical Screening
    - Thirty-eight (38) chemical parameters in soil and thirty (30) chemical parameters in groundwater were retained as COCs for the RA.
    - For the calculation of benzo(a)pyrene equivalent (B(a)PE), half detection limits were used in the calculation for concentrations that were reported as non-detect.
    - Future vinyl chloride concentration in groundwater was calculated to be 990µg/L.
    - Secondary screening is presented in Tables F1-3 through F1-5e screen against Table 2 S1, GW1, S-GW3, and GW3.

- Risk characterization
    - The RA identifies that a hazard quotient of 0.5 (for inhalation pathways only) for trichloroethylene is considered appropriate for the assessment.
    - Ingestion of groundwater: RA identified that “risks to offsite receptors (that is, offsite Construction and Utility Workers) were indirectly assessed through the modelling for onsite Construction and Utility Workers”.
    - The RA identified that the proposed Property Specific Standards (PSS) could exceed the Table 6 SCS for downgradient sites and as such, groundwater monitoring is proposed.
        - The following is provided in the RA: Offsite groundwater quality can be addressed onsite by monitoring groundwater movement, allowing natural attenuation, and notifying appropriate stakeholders in the event of offsite migration.
        - Based on the Phase Two CSM, groundwater flow in overburden and bedrock contact zone is northeast to southwest. The flow in the Eramosa formation is flow is east.
- RMMs were presented in Appendix I RMP engineering report: The following RMMS were proposed:
    - Physical barriers: Hard cap/fill cap; options to mitigate contaminant transport along utility corridors (e.g., trench plugs, anti-seep collars, trench liners, watertight shoring)
    - Vapour Intrusion Mitigation: Passive venting system; vapour proof barrier; and foundation and penetration sealing.
    - Groundwater monitoring was mentioned in the RA. TCE and other chlorinated degradation products were identified in groundwater on the eastern portion of the site in the overburn and bedrock contact zone and Eramosa Formation where the groundwater appears to flow to the east. Additionally, there are PHC exceedances in groundwater, corresponding to soil impacts in the area of the machine shop and excavation area. There is residual free phase product in this area. However, no discussion is provided regarding the movement of this off-site to the downgradient in the RMP and how this could be mitigated.

- Section 7 of the RA: Includes discussion on hard cap/fill cap; vapour intrusion mitigation with sub-slab or indoor air monitoring program prior to any building occupancy; health and safety plan; soil and groundwater management plan; groundwater control and management; land use restriction; building restriction associated with NAPL; groundwater monitoring program include wells along the downgradient perimeter of the site and compare concentrations to GW1 for the potable water considerations and implement a restriction of use of groundwater as a source of water. Implications to offsite human and ecological receptors will be assessed through groundwater monitoring.

- For Section 7.4.3.1: As per MECP comments, the groundwater monitoring program included monitoring wells OW24S/D and OW13-39S/D to monitoring COCs coming onto the property and ensure that they do not exceed the PSS. Wells OW23S, MW17-108S, and MW18-135S have been also been added to the groundwater monitoring program to monitor NAPL presence as these are within the areas identified as having residual NAPL.

- ERA
  - Primary routes of exposure that were semi-quantitatively evaluated are:
    - Soil organisms – ingestion and dermal contact with soil
    - Terrestrial plants—root uptake from soil and groundwater
    - Birds and mammals—ingestion of soil and food-chain transfer by the consumption of contaminated prey or forage items
  - Receptors utilized:
    - For onsite birds and mammals: American Woodcock, Red-winged Blackbird, and Red-tailed Hawk to represent birds; Meadow Vole, Red Fox, and Short-tailed Shrew to represent mammals.
    - Plants and soil organisms: grasses and Manitoba Maple trees, earthworms
  - Secondary screening for groundwater indicated that concentrations of ten (10) COCs (i.e., anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b&j)fluoranthene, benzo(k)fluoranthene, chrysene, PHC F1, PHC F2, pyrene and zinc) exceeded the Table 6 GW3 component value.
  - Ecological Risk-based Target Concentrations were developed based on the lowest of the selected EcoBMCs used in the ERA (for plants and soil organisms or birds and mammals) or the higher of the lowest EcoBMC and the Table 6 SCS (so that the selected values are not more stringent than MECP generic standards). Fill cap target concentration was developed by using the Ecological Risk-based Target Concentrations.

Hello Alexina,
Please see the response to Comment 18 below in blue. The associated text edits adding the potential hazards from inhalation of iron dusts are shown in tracked changes (red) in the attached PDF of Section 4. Please see PDF pages 42 (*Section 4.4.3.5 – Qualitative Assessment of Parameters without Toxicity Data, Iron [Dust Only]*) and 57 (*Section 4.5 – References*) for the edits.

Figure 7-2 is also attached to address the RMP comment.

Please let me know if these additional materials/edits satisfy the comments, or if additional information is required.

Katherine

Subject: [EXTERNAL] Request for Additional Information - RA for 200 Beverley Street, Guelph, Ontario [RA1748-19c; IDS#6417-B9XQGZ]

Hi Katherine,

The Ministry's review of the above listed risk assessment is currently ongoing. In order for the Ministry to complete its review, it is requested that the following information/clarification be provided:

New Risk Assessment Comment (September 2021)

18. Section 4.4.3.5 – Regarding the issue of iron dust, it should be clarified that there is a known hazard associated with chronic inhalation of iron dust (and the nature of the hazard should be noted) and this is being evaluated qualitatively based on the elevated exposure relative to background. Since elevated exposures may occur in the absence of risk management measures, it has been assumed that potentially unacceptable risks may occur and risk management measures are therefore prompted (i.e., capping). The Reviewer assumes this is the QP's intent. Please clarify.

Jacobs Response: According to the US EPA (2006)[1] there is inadequate data to derive a reference concentration (RfC) for exposure to iron via inhalation. However, the hazards associated with occupational exposures to iron may include "irritation to eyes, skin, and respiratory tract" (from inhalation of aerosols or mists of soluble iron salts); "siderosis, a benign pneumoconiosis" and "accumulation of iron dust in the lungs" (from inhalation of ferric oxide dusts and fumes). There is conflicting evidence regarding the carcinogenicity of humans from iron via inhalation routes of exposure; however, the US EPA has classified iron and its compounds as a "possible human carcinogen". There is inadequate data to derive a unit risk factor (URF) for exposure to iron via inhalation. The specific hazard information has been added to Section 4.4.3.5, along with the associated US EPA reference to Section 4.5, please see the attached PDF.

As mentioned in Section 4.4.2.9, a quantitative assessment of iron via dust inhalation could not completed due to a lack of appropriate TRVs; therefore, a qualitative assessment using background values was completed in Section 4.4.3.5. The qualitative assessment concluded that risks to human receptors via the inhalation of iron in dust could potentially pose a risk because concentrations of iron in soil are greater than background in some areas of the Site. Therefore, RMMs are required to prevent or reduce dust generation at the Site. As noted in Table 4-40, the RMMs specifically required for iron in soil are listed as: Surface Cover for Site Users; Dust Suppression During Construction Activities; and PPE for Subsurface Workers.

4. Human Health Risk Assessment

This section of the risk assessment (RA) primarily evaluates risk to human health at the RA Property by addressing the elements required in the RA process. Jacobs completed a quantitative and qualitative Human Health Risk Assessment (HHRA) and deemed the level of risk to be appropriate based on the RA Property's existing conditions and anticipated future use, and the implementation of a risk management plan (RMP). HHRAs assess the potential for human health risks resulting from contamination and the presence of contaminants of concern (COCs) at a site.

This HHRA adheres to the prescribed Ontario Regulation (O. Reg.) 153/04 (as amended) (MECP, 2011a) reporting format and includes the following four major elements:

1) Problem Formulation
2) Exposure Assessment
3) Hazard Assessment
4) Risk Characterization

4.1 Problem Formulation

4.1.1 Human Health Conceptual Site Model

The previously identified risk components, namely chemicals detected, site-specific soil characteristics, pathways, and receptors, as well as proposed redevelopment conditions, are combined to synthesize the conceptual site model (CSM) for the HHRA. The CSM is used to direct the quantitative and qualitative assessments to complete the RA. This section describes elements considered in the development of the CSM.

Receptors have been identified under pre- and post-redevelopment situations, independent of the screening of COCs. This is so that the most conservative scenarios for the RA Property are considered and modelled quantitatively, if necessary. Jacobs understands the RA Property will be redeveloped into mixed residential, parkland, and commercial use. Consequently, Jacobs considered residential and commercial development scenarios while identifying receptors and potentially complete exposure pathways. Residential exposures are protective of parkland exposures.

The following onsite receptor types have been identified for the CSM:

- Residents
- Site Visitors
- Indoor Workers
- Construction Workers
- Utility Workers
- Outdoor Workers

Offsite potential receptors include the following:

- Surface Receptors[1]
- Construction Workers
- Utility Workers

[1] Surface Receptors incorporate offsite surface receptors (that is, receptors not engaged in subsurface excavation activities), such as Residents, Visitors, Outdoor Workers, or Patrons of nearby properties who may be exposed to dust (soil particulates) migrating offsite during the redevelopment of the RA Property in the absence of risk management measure (RMMs).

Onsite Outdoor Worker, Indoor Worker, Site Visitor, and Resident receptors could be exposed to surface soil. Onsite Construction and Utility Workers receptors could be exposed to surface and subsurface soil. Offsite receptors could be exposed to COCs migrating offsite through soil particulate or groundwater migration. Groundwater is not typically accessible to receptors other than Construction and Utility Workers. Section 4.2.1 provides additional details on potential receptors.

Figure 4-1 presents the Human Health CSM that was developed for the RA Property under current and proposed future conditions. It was based on, and is consistent with, information gathered during site investigation activities and visits described in Section 3 and Appendix D. Section 4.2 describes in more detail how the Human Health CSM was developed and used in the HHRA. Figure 4-2 illustrates the Human Health CSM that is relevant after the RMP in Section 7 of this document is implemented.

4.1.2 Contaminant of Concern Screening for Human Health

Chemical screening incorporates elements of toxicity analysis and exposure assessment by selecting screening criteria that have previously been developed through an RA approach. Risk-based screening criteria use toxicity reference values (TRVs) derived by regulatory agencies in Canada and the United States (U.S.). Regulatory agencies use TRVs to back-calculate standards considered protective of various land uses. The risk-based standards also incorporate assumptions regarding the most sensitive receptor characteristic, such as body weight (BW), ingestion rate, and exposure duration (ED) (based on land use). Chemical screening was conducted to focus the number of retained COCs for the quantitative HHRA.

As presented in Section 3.3, Contaminants of Concern, parameters in soil and groundwater were screened against the Ministry of the Environment, Conservation and Parks (MECP's) *Table 6: Generic Site Condition Standards for Shallow Soils in a Potable Groundwater Condition* for Residential/ Parkland/ Institutional/ Industrial/ Commercial/Community property use (Table 6 SCS) (MECP, 2011c) based on detected concentrations and method detection limits (MDLs) (refer to Tables F1-1 and F1-2 in Appendix F). This screening process identified the set of COCs requiring evaluation in both the HHRA and ecological risk assessment (ERA).

The following subsections outline the secondary screening process for human health and identify which COCs were assessed quantitatively or qualitatively.

Estimated Site Maximums. Jacobs used estimated Site maximums to complete the secondary human health screening and risk calculations; the approach was inferred from information provided in the Modified Generic Risk Assessment (MGRA) model spreadsheet (MECP, 2016a; 2016b). The MGRA model spreadsheet accepts an estimated maximum concentration up to 20 percent greater than the measured maximum. The estimated Site maximums were, therefore, derived by applying the greater of the maximum detected concentration, multiplying it by 1.2 and then rounding it down to two significant digits, as appropriate, or by applying the MDL. Jacobs did not apply this calculation to COCs with observed maximum concentrations based on an MDL.

Chemical Fate and Transport. The potential fate and transport of a chemical is characterized, in part, by its physical and chemical properties. Water solubility predicts the amount of a chemical that will dissolve in water. The soil sorption coefficient predicts the ratio of the chemical mass that will adsorb to soil versus the mass that will dissolve in soil pore water. The vapour pressure of a chemical can indicate the likelihood that a chemical will volatilize from its pure compound state; chemicals with high vapour pressures are expected to readily volatilize. The Henry's Law Constant (H) for a chemical indicates the theoretical amount of a chemical that will volatilize from the dissolved water phase to the vapour phase; chemicals with high H (that is, greater than 1×10^{-5} [atmospheres per cubic metre per mol [atm-m^3/mol]) or a high vapour pressure (that is, greater

than 1.0 Torricelli [Torr] [Blok, 2019, pers comm.]) are expected to volatilize. Inorganics were not considered volatile; therefore, they were not retained for the vapour inhalation (VI) pathway. The heavier petroleum hydrocarbons (PHCs) (that is, PHC F3 and PHC F4) were also not considered volatile, and were not retained for the VI pathway. Additional details on the volatility designation of parameters are presented in Appendix F2.

As part of the exposure assessment, these values are examined for each COC to evaluate the potential for migration and to model the movement of COCs from the subsurface to a receptor along a potentially complete exposure pathway. Chemical properties provided in the Rationale Document (MECP, 2011a) were used in this assessment unless otherwise indicated. Jacobs used the chemical properties provided in the Rationale Document (MECP, 2011b) in this assessment, unless otherwise indicated.

Tables 4-1 and 4-2 present the estimated maximum concentrations for soil and groundwater. Section 4.1.2.1 describes the secondary screening process for soil.

4.1.2.1 Soil Screening

Parameters were retained for *quantitative* analysis related to direct contact exposure to soil if the parameter was selected as a COC through the screening process in Section 3.3 and its estimated site maximum concentration is greater than the S1 (direct contact) component values used to derive the Table 2 *Full Depth Generic Site Condition Standards in a Potable Ground Water Condition* for coarse-grained soils and residential/parkland/institutional land use (Table 2 Standard) (Appendix F1, Table F1-3).

Parameters were retained for *quantitative* analysis related to inhalation of dust particulate if the parameter was selected as a COC through the screening process in Section 3.3, and the parameter was retained for direct contact exposure to soil (that is, the estimated maximum concentration is greater than the Table 2 S1 component value) (Appendix F1, Table F1-3).

Jacobs employed a two-step screening process for the selection of parameters to be retained for *quantitative* analysis related to inhalation of volatiles through the soil-to-indoor-air (S-IA) pathway and the soil-to-outdoor-air pathway[2] (including inhalation in a trench). Appendix F2 provides additional details on the volatility designation of the COCs (Appendix F2, Table F2-1) and the screening process applied to soil COCs determined to be volatile (Appendix F2, Table F2-2).

COCs and pathways that were not retained for quantitative assessment were, therefore, retained for qualitative assessment. Refer to Section 4.4.3. Table 4-1 summarizes the pathways to be retained for each COC resulting from the secondary screening. Appendix F1, Table F1-3 and Appendix F2, Table F2-2 provide the detailed screening for non-volatile COCs and volatile COCs, respectively.

4.1.2.2 Groundwater Screening

Parameters were retained for *quantitative* analysis related to direct contact exposure to groundwater (for Construction and Utility Workers) and potable water use for Residents if the parameter was selected as a COC through the screening process in Section 3.3, and its estimated site maximum concentration is greater than the GW1 (direct contact) component value used in the derivation of the Table 2 Standard (MECP, 2011a) (Appendix F1, Table F1-4).

Jacobs employed a two-step screening process for the selection of parameters to be retained for quantitative analysis related to inhalation of volatiles through the groundwater- to-indoor-air (GW) pathway and the groundwater-to-outdoor-air pathway (including inhalation in a trench). Appendix F2 provides additional

[2] Appendix G2 provides the rationale for why the MECP outdoor air (OA) component values were not specifically used in the RA.

details on the volatility designation of the COCs (Appendix F2, Table F2-1) and the screening process applied to groundwater COCs determined to be volatile (Appendix F2, Table F2-2).

COCs and pathways that were not retained for quantitative assessment were, therefore, retained for qualitative assessment. Refer to Section 4.4.3. Table 4-2 summarizes the results of the secondary screening. Appendix F1, Table F1-4 and Appendix F2, Table F2-2 provide the detailed screening for non-volatile COCs and volatile COCs, respectively.

4.1.2.3 Additional Considerations Applicable to the Human Health Risk Assessment

Approach for Polycyclic Aromatic Hydrocarbons

The MECP uses a toxicity equivalence factor (TEF) approach to assess risks related to environmental mixtures of carcinogenic polycyclic aromatic hydrocarbons (PAHs). Jacobs reviewed Canadian Council of Ministers of the Environment (CCME) guidance on PAHs when selecting an approach to assess risks related to environmental mixtures of carcinogenic PAHs (CCME, 2010).The MECP guidance indicates that when it is possible for exposure to a PAH mixture to occur at a site, the combined carcinogenic risk from all PAHs with the same mode of action must be assessed, even if an individual PAH is present at a concentration less than its individual SCS.

The TEF approach to assessing potential carcinogenic risks related to environmental mixtures of PAHs is based on evaluating the relative toxicity of carcinogenic PAHs to benzo(a)pyrene (B(a)P). Table 4-3 presents the TEFs applied in this assessment.

To assess the combined carcinogenic risk from all PAHs at the RA Property, a total toxicity equivalence concentration (Washington Department of Ecology, 2008) or benzo(a)pyrene equivalent (B(a)PE) (Law et al., 2002) must be developed as follows:

$$B(a)PE = \sum(Cn \times TEFn) \qquad (1)$$

Where:

Cn = Concentration of the individual carcinogenic PAH in the mixture (micrograms per gram [µg/g] for soil and micrograms per litre [µg/L] for groundwater)

TEFn = Toxic equivalency factor of the individual carcinogenic PAH in the mixture

For each sample (soil or groundwater) analyzed for PAHs, a B(a)PE value was calculated per Equation (1). Half detection limits were used in the calculation for concentrations that were reported as nondetect. The calculated B(a)PE values were evaluated, and the maximum B(a)PE concentration was retained for use in the RA (Table 4-4). The estimated maximum concentration was applied (maximum result multiplied by 1.2), to produce a B(a)PE for soil of 282 µg/g and a B(a)PE for groundwater of 10.3 µg/L.

As contact with PAHs may occur through the dermal, ingestion, and dust-inhalation pathways, these pathways were evaluated using the B(a)PE. Results for these parameters appear as B(a)PE within the tables and text in Section 4.

Approach for Canadian Council of Ministers of the Environment Petroleum Hydrocarbons

The MECP has adopted the CCME Tier 1 standards for petroleum hydrocarbons (PHCs) in soil (CCME, 2008), and included them in the O. Reg. 153/04 Standards (as amended). Assumptions are available to

estimate appropriate concentrations of CCME subfractions, based on the available gross PHC measurements. For PHCs in soil, the CCME determined proportions for the 14 subfractions considered in the Total PHC Criteria Working Group (TPHCWG) (1997a,b; 1998a,b; 1999) approach within the four CCME fractions, based on published data. Table 4-5 summarizes these proportions, which were applied to the PHC fraction soil sampling results and used to evaluate the associated risk.

For PHC in groundwater, Health Canada has identified proportions for the 14 subfractions within the four CCME fractions in the *Preliminary Quantitative Risk Assessment (PQRA) Guidance Part IV* (Health Canada, 2008). Table 4-6 summarizes these proportions, which were applied to the PHC fraction groundwater sampling results and used to evaluate the associated risk.

Approach for Parameters without Toxicity Data

Human health toxicity data may not be available for all parameters evaluated in the HHRA. Refer to Section 4.4.3.5 for the qualitative assessment of electrical conductivity (EC) and lead, which do not have human health toxicity data.

Approach for Vinyl Chloride in Groundwater

In accordance with the *Rationale Document* (MECP, 2011b), the RA evaluated the potential for chlorinated ethylene concentrations in groundwater to degrade to vinyl chloride (VC). As the MECP guidance document discusses, the anaerobic biodegradation of chlorinated compounds to VC involves a reductive dechlorination step, which is influenced by chemical-specific parameters (that is, solubility) and site-specific geochemical parameters (that is, oxidation-reduction [redox] potential). The following chlorinated parent compounds are known to degrade to VC through reductive dechlorination (MECP, 2011b):

- Trichloroethylene (TCE)
- Tetrachloroethylene (PCE)
- 1,1-Dichloroethylene (1,1-DCE)
- cis-1,2-Dichloroethylene (cis-1,2-DCE)
- trans-1,2-Dichloroethylene (trans-1,2-DCE)

To account for the potential degradation of parent compounds to VC at the RA Property, the maximum concentrations of the parent compounds were summed, and 10 percent of the sum was added to the maximum VC concentration (identified as the greater of the detected concentration and MDL) to produce a potential VC concentration. An estimated maximum VC concentration was also derived by either multiplying the maximum detected VC concentration by 1.2 (if the maximum detected concentration exceeded the MDL), or applying the maximum VC detection limit. The greater of the potential VC concentration and estimated maximum VC concentration was applied as the input value in the risk calculations. Using the greatest VC concentration from these two methods provides a conservative estimate of potential future site-related risks by accounting for the potential degradation of VC parent compounds.

Table 4-7 summarizes concentrations of VC and its parent compounds in groundwater as well as the development of the potential VC concentration and compares this value to the estimated maximum VC concentration. The input value for modelling and risk calculations for the RA Property groundwater used a VC concentration of 990 µg/L, based on the estimated maximum concentration.

Approach for the Presence of Nonaqueous Phase Liquid

Over the course of the Phase Two investigation activities, nonaqueous phase liquid (NAPL) was measured in three locations: OW23S, MW17-108S, and MW18-135S. NAPL has been measured at OW23S (screened from 2.52 and 5.26 metres below ground surface [mbgs]) at thicknesses of 0.005 to 0.97 m in 21

monitoring events between 2010 and 2020. At MW17-108S (screened from 1.93 and 4.98 mbgs), NAPL has been measured at thicknesses of 0.002 and 0.18 m in six monitoring events between 2017 and 2020. At MW18-108S (screened from 4.27 to 5.79 mbgs), NAPL has been measured at thicknesses of 0.02 and 0.93 m in five monitoring events between 2019 and 2020.

The presence of NAPL could have implications for the risk evaluations that rely on the application of partitioning equations (that is, movement to indoor and outdoor air). Direct contact exposure to NAPL itself would also be possible if NAPL was present. The MECP SCS and component values considered in the evaluation of soil and groundwater COCs, and the equations applied in the calculations of risk and hazard, assume that NAPL-associated contaminants (such as PHCs; benzene, toluene, ethylbenzene, and xylenes (BTEX); and PAHs) are distributed between the dissolved, vapour, and sorbed phases (that is, three phases are considered). If NAPL is present, an additional fourth phase must be considered. Section 4.4.3.6 qualitatively evaluates the potential risks to human health from NAPL.

4.1.3 Risk Assessment Objectives

The objective of the HHRA is to estimate the potential health risks to human receptors from the COCs identified in RA Property soil and groundwater in the absence of RMMs. The RA Property is currently proposed to be redeveloped into mixed residential, parkland, and commercial use. As such, the HHRA assessed the following receptors:

- Residents
- Site Visitors
- Construction Workers
- Utility Workers
- Outdoor Workers
- Indoor Workers

As detailed in the CSM, the assessment included exposure pathways related to the ingestion of, dermal contact with, and the inhalation of COCs originating from impacts in soil or groundwater.

Risk is assessed both quantitatively and qualitatively. Quantitative risk characterization is conducted to evaluate the noncancer hazard and cancer risk posed by Site COCs to each receptor for identified potentially complete pathways. In some cases, the risk was assessed qualitatively, based on the exposure of certain receptors being protected by quantitative evaluation of a more sensitive receptor, and based on select pathways being demonstrated to be incomplete. The quantified levels of risk were used to determine whether RMMs are required at the Site. Property-specific Standards (PSSs) were also determined as required.

Human health risks and hazards were calculated for the RA Property following a standard RA approach under O. Reg. 153/04. Section 1.1.1 describes the general framework for carrying out the RA.

4.1.3.1 Jacobs Quality Control and Data Quality Objectives

Soil and groundwater sampling was either performed or supervised by Jacobs staff with experience in intrusive field investigation techniques and with the COCs encountered at the Site, under the supervision of a MECP Qualified Person for ESAs (QPESA). Soil and groundwater sampled by Jacobs between 2017 and 2020 were collected according to our standard operating procedures (SOPs), which were developed in accordance with O. Reg 153/04 (MECP, 2011a). The selected analytical laboratories performed the chemical analysis in compliance with the MECP's Laboratory Services Branch *Protocol for Analytical Methods Used in the Assessment of Properties under Past XV.1 of the Environmental Protection Act,* as amended (MECP, 2011d).

In combination with the field QA/QC program, a Jacobs project chemist has completed an evaluation of the laboratory QA/QC program to verify the accuracy, precision, and validity of the data reported by the laboratory. Various elements of the laboratory QA/QC program are used to evaluate the data: blanks are analyzed to detect laboratory contaminations that can cause data to be biased high; laboratory control samples are used to evaluate the laboratory performance; laboratory duplicates are used to measure precision in the laboratory; matrix spikes are used to identify high or low bias caused by matrix interference; and surrogate spikes are used to evaluate the method performance that can cause high or low bias in the data. Evaluation of the laboratory QA/QC program was performed by examining blanks, laboratory control samples, matrix spikes, and surrogate spike samples.

The groundwater and soil analytical data evaluated herein is considered valid. All results can be used to support the project decision making process. Appendix D2 provides additional details on the QA/QC program.

The current database includes soil and groundwater data from past investigations completed by other consultants. As discussed in Section 3.3.2, Jacobs determined that some historical soil data are useful for inclusion in the RA report. Appendix D2 lists the historical reports which were included as part of the Phase Two ESA.

Since the intent is to manage the potential risk associated with soil and groundwater contamination in place by using engineering controls as necessary, Jacobs considers the data collected to be adequate. Uncertainties associated with data quality are not likely to affect the objectives of the RA or the ability of current and future land owners to manage potential risks at the RA Property. Overall, the quality of data used in the RA were considered sufficient to meet the objectives of the HHRA and to be usable for RA decision making.

4.2 Exposure Assessment

The exposure assessment quantifies or estimates the potential exposure to environmental media (for example, groundwater or air) in which humans could possibly have contact with COCs at the RA Property under current and future scenarios. This section also presents the methodology used to estimate exposure concentrations, the equations and models, as well as the exposure assumptions used for the retained exposure pathways.

4.2.1 Receptor Characteristics

For this RA, receptor assumptions have been compiled for human characteristics for use in quantitatively or qualitatively determining the various exposure doses or exposure concentrations. MECP (2011b) or Canadian-specific values were used where available. Other sources of human factor parameters included information generated by the U.S. Environmental Protection Agency (EPA), which Jacobs adopted and used here based on an understanding of similarities between U.S. and Canadian populations. If a piece of information could not be obtained from a credible source, Jacobs assumed a conservative estimate based on professional and scientific judgment. Section 4.2.3, Exposure Estimates, describes the characteristics of each retained receptor by pathway.

The proposed future use of the RA Property is mixed residential, parkland, and commercial. Based on this proposed future use, the receptors included in the HHRA for quantitative and qualitative assessment are presented in Table 4-8.

Where appropriate, Jacobs used a composite human receptor. This means a lifetime of exposure and risk was evaluated based on adjusted age characteristics calculated using a weighted average for each parameter from each of the five life stages summed to derive a composite value.

Individual descriptions for each receptor considered in the HHRA are as follows:

- **Resident** – The Resident is assumed to be an infant, toddler, child, teen, adult, or composite receptor residing within a proposed residential building. The Resident is anticipated to spend the majority of his or her time indoors but would also spend a limited amount of time outdoors within the RA Property. The Resident could be exposed to soil via direct contact (incidental ingestion, dermal contact, and dust inhalation), to potable groundwater via direct contact (ingestion of drinking water and dermal contact), via the inhalation of indoor air (that is, the migration of volatile COC vapours from soil and groundwater to indoor air), and via the inhalation of vapours in outdoor air (COC vapour emissions from soil and groundwater to outdoor air). The Resident is anticipated to be present onsite 24 hours a day, 7 days a week, 50 weeks per year, for 76 years.
- **Site Visitor** – The Site Visitor is assumed to be an infant, toddler, child, teen, adult, or composite receptor visiting the RA Property for residential, parkland, or commercial purposes. The Site Visitor could be exposed to soil via direct contact (incidental ingestion, dermal contact, and dust inhalation), to potable groundwater via direct contact (ingestion of drinking water and dermal contact), and via the inhalation of vapours in outdoor air (COC vapour emissions from soil and groundwater to outdoor air). Site Visitor exposure to Site media is expected to be less than that of the Resident; therefore, exposure and risk to Site Visitors was qualitatively assessed in terms of the results for Residents. Site Visitors are conservatively assumed to be present onsite for a portion of each day, 7 days a week.
- **Construction Worker** – A Construction Worker is considered to be an adult worker conducting excavation activities extending to the water table, such as those that would occur during construction or redevelopment activities. The Construction Worker could be exposed to soil via direct contact (incidental ingestion, dermal contact, and dust inhalation); to groundwater via direct contact (incidental ingestion and dermal contact[3]); and via the inhalation of vapours in outdoor air (COC vapour emissions from soil and groundwater). The Construction Worker is anticipated to be onsite full-time, 5 days a week, for a limited number of years, and would represent a subchronic subsurface worker exposure scenario.
- **Utility Worker** – The Utility Worker is considered to be an adult worker conducting ground-intrusive activities that extend to the water table, such as those that would occur during the maintenance, installation, or repair of subsurface utilities. The Utility Worker could be exposed to soil via direct contact (incidental ingestion, dermal contact, and dust inhalation); to groundwater via direct contact (incidental ingestion and dermal contact[3]); and via the inhalation of vapours in outdoor air (COC vapour emissions from soil and groundwater). The Utility Worker is anticipated to be onsite full-time for a limited number of days per year, but for a significant number of years (that is, 56 years), thus represents an intermittent subsurface worker exposure scenario. This assumption is consistent with Health Canada (2004) which indicates 2 weeks per year for a construction worker, with the understanding that this receptor represents a utility worker, despite differences in naming convention.

[3] For the subsurface worker scenarios, it is expected that typical construction worker attire will be worn during these construction activities (for example, per O. Reg. 213/91, as amended [MOL, 1991]). With regards to groundwater contact, it is expected that typical construction activities, such as dewatering, will be performed (for example, per O. Reg. 213/91, as amended [MOL, 1991] which states that, "every excavation that a worker may be required to enter shall be kept reasonably free of water"). Given the use of dewatering techniques at construction sites (regardless of whether they are brownfields or not), which limits the presence of groundwater in construction areas, typical construction worker activities do not lead to extensive skin wetting. These typical construction activities are not considered risk management measures, as they are required by the Province of Ontario on every construction site, regardless of whether contamination is present or not.

- **Outdoor Worker** – The Outdoor Worker is considered to be an adult working primarily outdoors at the RA property to maintain landscaped areas. The Outdoor Worker could be exposed to soil by direct contact (incidental ingestion, dermal contact, and dust inhalation) and via the inhalation of vapours (COC vapour emissions from soil and groundwater) in outdoor air. As the average depth to groundwater (2.70 mbgs) is deeper than 1 mbgs, it is not expected that the Outdoor Worker would come into contact with groundwater during planting activities. The Outdoor Worker is conservatively anticipated to be onsite full-time (9.8 hours per day), 5 days a week, 39 weeks per year, for 56 years to tend to ornamental gardens and perform periodic landscape installations and grounds maintenance.
- **Indoor Worker** - The Indoor Worker is considered to be an adult working indoors within a future generic commercial building, with a limited amount of time spent outdoors. The Indoor Worker could be exposed to Site COCs via the inhalation of indoor air (migration of volatile COC vapours from soil and groundwater to indoor air). Exposures also considered include the inhalation of vapours in outdoor air (COC vapour emissions from soil and groundwater to outdoor air) and direct contact with Site soil (incidental ingestion and dermal contact). However, Jacobs notes that an Outdoor Worker would have greater exposure than the Indoor Worker to inhalation of vapours in outdoor air and direct contact with soil. Therefore, the risk to the Indoor Worker will be qualitatively assessed for these latter two pathways in the context of the Outdoor Worker. The Indoor Worker is anticipated to be onsite full-time (9.8 hours indoors per day), 5 days a week, 50 weeks per year, for 56 years.
- **Offsite Surface Receptors** – This receptor group incorporates offsite surface receptors (that is, receptors not engaged in subsurface excavation activities), such as Indoor Workers, Outdoor Workers, Site Visitors, Residents, patrons of nearby properties, or a combination thereof. Properties adjacent to the RA Property are generally used for industrial and commercial purposes. Approximately four residential properties are located to the west of the RA Property (cross-gradient), across Stevenson Street South. The Offsite Surface Receptors may be exposed to dust (soil particulates) migrating offsite during potential construction activities at the Site in the absence of RMMs. The movement of COCs offsite with groundwater flow may also contribute to a complete VI pathway (both indoors and outdoors) for offsite receptors. Offsite Outdoor Workers, Indoor Workers, Residents, or patrons of nearby properties are anticipated to be present offsite for the same amount of time as the corresponding onsite receptors. Therefore, exposure and risk to these offsite receptors are expected to be less than that of similar onsite receptors. These receptors were qualitatively assessed in terms of onsite Outdoor Workers, Indoor Workers, and Residents. These receptors were qualitatively assessed for the potential for risk from offsite migration of COCs.
- **Offsite Construction and Utility Worker** – This receptor group incorporates Construction and Utility Workers engaged in excavation activities downgradient of the RA Property that may be exposed to groundwater that has migrated offsite from the RA Property. Exposure and risk to these offsite receptors is anticipated to be less than that of similar onsite receptors; therefore, these receptors were qualitatively assessed in terms of the onsite results for Construction and Utility Workers.

Tables 4-9, 4-10, 4-11, and 4-12 present specific receptor assumptions (for example, BW, skin surface area, and ED) for receptors requiring quantitative assessment.

A Pregnant Female receptor was also included in the RA for quantitative assessment of risk related to COCs with developmental effects. For the direct contact pathways, this receptor is used in each quantitatively assessed exposure scenario that does not include a toddler (for example, Indoor Worker, Outdoor Worker, Construction Worker, and Utility Worker). The calculations for pregnant female receptors assume continuous exposure without prorating for exposure frequency (EF) or ED because an exposure limit may be exceeded during any one of many critical developmental periods during pregnancy. The exposure estimates for the Pregnant Female Worker or Pregnant Female Resident for each scenario were

then appropriately carried through for risk evaluation for COCs where Section 4.3.2.1 identifies potential developmental effects.

4.2.2 Pathway Analysis

A complete exposure pathway must exist for risk to be present at a site. An exposure pathway is the means by which a receptor may make contact with a COC from a site. A complete exposure pathway has the following five elements:

1) A source of chemical released to the environment (for example, PHC to soil)
2) A mechanism for release of the source (for example, volatilization of vapours)
3) An environmental transport medium (for example, air)
4) An exposure point (for example, a workplace)
5) A feasible route of exposure (for example, inhalation)

Exposure may occur when environmental media containing chemicals migrate or are physically moved from the site to an exposure point, such as a location where receptors can make contact with chemicals in environmental media. It may also take place when a receptor makes direct contact with the source material containing the COCs. An exposure pathway is complete (that is, there is exposure) if a receptor takes in chemical constituents through ingestion, inhalation, or dermal absorption (contact with the skin).

Direct contact with contaminants occurs when receptors make direct contact with the medium that contains the contaminants (for example, placing hands in water or touching soil with hands). Indirect contact with the contaminants occurs when the contaminants are transported from their presently identified location to a receptor through a variety of mechanisms (for example, the inhalation of indoor vapours originating from soil or groundwater).

This section discusses possible pathways of exposure to COCs by receptors on and off the RA Property. Incomplete or implausible pathways where there can be no exposure are not retained for the RA. Table 4-13 and Section 4.2.2.1 present the rationale for retaining or eliminating these pathways.

The potential soil and groundwater exposure pathways have been evaluated based on current Site conditions and considering future Site conditions following redevelopment.

4.2.2.1 Site-specific Pathway Analysis Summary

Table 4-13 presents the pathway analysis for the HHRA. Based on the Site characterization and chemistry, the current and proposed land use, and the anticipated receptors on the RA Property, Jacobs quantitively assessed the following exposure pathways and receptors:

- Ingestion and dermal contact with soil and groundwater
- Inhalation of volatiles in indoor air (derived from soil and groundwater)
- Inhalation of volatiles in outdoor air (derived from soil and groundwater)
- Inhalation of particulates (dust derived from soil) in outdoor air

Jacobs performed risk calculations for the maximally exposed receptor and pathway scenarios, as indicated in the Rationale column of Table 4-13. Jacobs qualitatively evaluated potential risks to receptors and pathways not specifically modelled from the maximally exposed quantitative results.

The following paragraphs discuss the pathways that are complete but were not quantitatively assessed.

Direct Contact Exposure—Vapour Skin Contact

Dermal exposure to vapours may be a significant pathway of exposure to chemicals in some cases; however, this pathway was not assessed in the HHRA because of the uncertainties associated with the numerous assumptions required to quantify the exposure. For example, the equations available for quantifying dermal absorption of chemical vapours are typically simplistic (and often inaccurate), as they do not account for variability of skin penetration, variability of skin exposure, temperature and humidity, and evaporation from skin following deposition onto skin. As such, while dermal exposure to vapours is a potentially complete pathway at the RA Property, given the uncertainty associated with the quantification of this pathway and the general belief that it does not contribute greatly to a receptor's overall exposure and body burden unless he or she is wearing a respirator (which is not anticipated at the RA Property), this pathway is not quantitatively evaluated. A qualitative assessment of the dermal exposure to vapours pathway is presented in Section 4.4.3.3.

Non-Aqueous Phase Liquid Exposure

As discussed in Section 4.1.2.3, NAPL has been identified at the RA Property, and there is potential for it to remain following redevelopment. The presence of NAPL could have implications for the risk evaluations that rely on the application of partitioning equations (that is, movement to indoor and outdoor air). Direct contact exposure to NAPL itself would also be possible where NAPL is present. Section 4.4.3.6, discusses the qualitative assessment of NAPL at the RA Property.

Ingestion Exposure— Home Grown Garden Produce

The ingestion of home-grown garden produce may be a significant pathway of exposure to chemicals in some cases; however, this pathway was not quantitatively assessed in the HHRA because of the uncertainties associated with the numerous assumptions required to quantify the exposure. For example, there is a significant amount of uncertainty associated with the uptake of certain soil COCs into the edible portions of plants. In addition, factors such as the potential yield of an urban garden, the amount and type of produce consumed, and the effects of various methods of food preparation are difficult to quantify. While it is not anticipated that a significant portion of a Resident's normal diet would be derived from home garden produce, potential risks can be mitigated by implementing the use of RMMs that limit or prohibit gardens that produce fruits and vegetables for consumption, or by requiring that home gardens only be grown in containerized plots or aboveground containers. Therefore, this pathway is not quantitatively evaluated. A qualitative assessment of this pathway is presented in Section 4.4.3.7.

Qualitative Assessment of Inhalation of Soil Particulates that are Ingested

Exposure from COCs in soil can occur from inhalation via two primary routes of exposure. Smaller particulates (less than or equal to PM_{10}) may be inhaled into the lungs and larger particulates (greater than PM_{10} and less than PM_{30}) may be trapped in the upper respiratory tract and subsequently swallowed and ingested (MassDEP, 2008). The portion of this pathway where particulates reach the lungs has been quantitatively assessed in Section 4.4.3.8. However, the particulate ingestion portion is considered negligible relative to the ingestion exposure experienced by a receptor via the conventional incidental ingestion of soil pathway (refer to Section 4.4.2.4). Exposure from particulate ingestion may be a significant pathway of exposure to chemicals in some cases; however, for typical construction projects using MECP default assumptions (as is the case for this RA), the exposure and risk from this pathway is negligible. Therefore, this pathway was not quantitatively assessed. A qualitative assessment of this pathway is presented in Section 4.4.3.8.

4.2.3 Exposure Estimates

This section summarizes the methodology and exposure factors used to estimate dose concentration. Exposure estimates were calculated for the human health exposure pathways that were retained through the screening process. Daily intake (DI) and daily uptake (DU) are defined as the product of chemical concentration in the source material, multiplied by the amount of intake or uptake (or source material the body contacts or adsorbs), respectively.

$$Dose = Chemical\ Concentration \bullet Intake\ (or\ uptake) \quad (2)$$

Intake is generally used to describe administered doses (ingestion and inhalation), while uptake refers to absorbed doses (dermal).

Eight basic factors are used to estimate intake (or uptake):

1) C = Chemical concentration (milligrams per kilogram [mg/kg], µg/g, milligrams per litre [mg/L], milligrams per cubic metre [mg/m^3], or micrograms per cubic metre [µg/m^3])
2) CR = Contact rate; the amount of contaminated medium contacted (milligrams [mg], litres [L], or cubic centimetres [cm^3] per hour or day)
3) ET = Exposure time (hours per day) for *continuous* exposures (that is, inhalation)
4) EF = Exposure frequency (days per week, weeks per year)
5) ED = Exposure duration (total years)
6) BW = Body weight
7) AT = Averaging time (associated with the period of exposure and effects)
8) RAF = Relative absorption factor

Daily absorbed or administered dose (DAD) can be described by the following general equation:

$$DAD = \frac{C * CR * ET * EF1 * EF2 * ED * RAF}{BW * AT} \quad (3)$$

In this assessment, intake (or uptake) is normalized for time and BW, and is expressed in milligrams of chemical per kilogram of BW per day (mg/kg/d). This calculation has been completed for all exposure routes except inhalation, according to the MECP (2011b) (after [EPA, 2009]).

The chemical concentration (C) used for each exposure route was determined and discussed in previous sections. The CR for each exposure point is discussed in Sections 4.2.3.2 through 4.2.3.6.

Appendix G1 provides sample calculations for the exposure estimates referenced in this section. Calculations were performed using Microsoft Excel.

4.2.3.1 Dose Estimation for Carcinogens and Noncarcinogenic Effects

The intake of a chemical evaluated for carcinogenic health effects is averaged over an entire lifespan (that is, lifetime average chemical intake) of 56 years for workers. For carcinogens, the lifespan in years is referred to as the AT. The selection of an AT that spans a lifetime is based on EPA guidance (1989): *"The approach for carcinogens is based on the assumption that a high dose received over a short period of time is equivalent to a corresponding low dose spread over a lifetime."*

Typically, EPA recommends 70 years for residents as the AT for carcinogens; however, Health Canada recommends 75 years (Health Canada, 2010). The MECP has used 76 years to account for ages 0 to 75, inclusive, for lifetime exposure of residents (MECP, 2011b); as such this value was applied in this RA for Recreational Users. The MECP has used 56 years to account for ages 20 to 75, inclusive, for lifetime exposure of adult workers (MECP, 2011b); this value was applied in this RA for those receptors. For carcinogens:

$$AT = 56 \text{ years} \times 365 \text{ days/year} \quad (4)$$

The intake of chemicals evaluated for noncarcinogenic health effects uses an AT based on the estimated period of exposure for any given exposure setting.

For noncarcinogens:

$$AT = ED \times 365 \text{ days/year} \quad (5)$$

The noncarcinogenic risk is evaluated for a target receptor (the group within a potentially exposed population with the greatest potential exposure; that is, the group that receives the greatest intake).

Table 4-9 presents general receptor characteristics, such as BW, ED, and ATs. These inputs are also used in the specific equations that estimate dose for dermal, ingestion, and inhalation pathways, which are described in the following sections.

4.2.3.2 Dermal Uptake

Soil

A receptor's average uptake of COCs through dermal contact with soil, or DAD, is estimated using the following equation (based on MECP, 2011b):

$$DAD = \frac{C * DAF * SAF * ESSA * CF * EF1 * EF2 * ED}{BW * AT} \quad (6)$$

Where:

DAD = Daily absorbed or administered dose via dermal contact (mg/kg/d)

C = Chemical concentration in soil (mg/kg)

SAF = Soil adherence factor (mg per square centimetre [cm^2] per day)

DAF = Dermal absorption factor (unitless)

ESSA = Exposed skin surface area (cm^2)

CF = Conversion factor (10^{-6} kilograms per milligram [kg/mg])

*EF*1 = Exposure frequency (weeks per year)

*EF*2 = Exposure frequency (days per week)

ED = Exposure duration (years)

BW = Body weight (kilograms [kg])

AT = Averaging time (days)

This calculation of DAD via dermal contact assumes one soil contact event per day. Table 4-10 summarizes the values used to estimate the daily dermal uptake from soil.

Groundwater

A receptor's average uptake of COCs through dermal contact with groundwater is estimated using the following equation (based on EPA, 2004):

$$DAD = \frac{DA_{event} * FE * ESSA * EF1 * EF2 * ED}{BW * AT} \quad (7)$$

Where:

DAD = Daily absorbed or administered dose (mg/kg/d)

DA_{event} = Absorbed dose per event (mg/cm^2/event); the equations applied in the derivation of DA_{event} are presented in Appendix G1

FE = Frequency of events (event per day)

ESSA = Exposed skin surface area (cm^2)

*EF*1 = Exposure frequency (days per week)

*EF*2 = Exposure frequency (weeks per year)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging time (days)

The value of DA_{event} depends on the physical and chemical properties of the chemical being assessed (for example, dermal permeability factors, organic or inorganic chemical), event duration, concentration of the chemical in groundwater, and other factors. A discussion of the details for modelling exposure from this route can be found in the EPA's final *Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment)* (RAGS E) (EPA, 2004). This model estimates the rate of migration of a chemical through a receptor's skin during contact with impacted groundwater. Dermal permeability values (K_p), derived from either experimentally measured or predicted values, are used together with Site-specific receptor exposure characteristics to estimate exposure.

The potential for Construction or Utility Workers to make contact with contaminated groundwater is low, since typical construction methods (that is, dewatering) restrict prolonged contact with groundwater that may be present onsite. Exposure assumptions for Construction and Utility Worker contact with groundwater are included in Table 4-10.

Relative Absorption Factors

Relative absorption factors (RAFs) were used in this assessment. The terms dermal absorption factor (DAF) and gastrointestinal absorption factor (GIAF) are used in this assessment for dermal and ingestion exposures, respectively. The values are consistent with the values used by the MECP in the development of the 2011 Standards (MECP, 2011b) or in EPA RAGS E (2004), if a MECP value was not available. If a suitable RAF value for a COC could not be determined, absorption was assumed to be the same as that in the TRVs critical study (that is, 100 percent or an RAF of 1.0). Table 4-14 presents the RAFs used in the assessment.

Dermal Exposure Estimates

Tables 4-15 and 4-16a/b show the predicted dermal exposures to soil and groundwater (potable and subsurface contact), respectively.

4.2.3.3 Ingestion

Soil

A receptor's average uptake of COCs through incidental ingestion of soil is estimated using the following equation (MECP, 2011b; EPA, 1989):

$$DAD = \frac{C * IR_S * GIAF * CF * EF1 * EF2 * ED}{BW * AT} \quad (8)$$

Where:

DAD = Daily absorbed or administered dose via incidental ingestion (mg/kg/d)

C = Chemical concentration in soil (mg/kg)

IR_S = Quantity of soil ingested daily (milligrams per day [mg/d])

GIAF = Gastrointestinal absorption factor (unitless)

CF = Conversion factor (10^{-6} kg/mg)

*EF*1 = Exposure frequency (weeks per year)

*EF*2 = Exposure frequency (days per week)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging time (days)

Table 4-14 summarizes the GIAFs used to estimate the ingestion intake from soil.

Groundwater

A receptor's average uptake of COCs through incidental ingestion of groundwater is estimated using the following equation (MECP, 2011b; EPA, 1989):

$$DAD = \frac{C * IR_W * GIAF * FE * CF * EF1 * EF2 * ED}{BW * AT} \quad (9)$$

Where:

DAD = Daily absorbed or administered dose (mg/kg/d)

C = Chemical concentration in groundwater (µg/L)

IRW = Quantity of groundwater ingested daily (L per event)

GIAF = Gastrointestinal absorption factor (unitless)

FE = Frequency of events (events per day)

CF = Conversion factor (0.001 milligram per microgram [mg/µg])

*EF*1 = Exposure frequency (weeks per year)

*EF*2 = Exposure frequency (days per week)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging time (days)

Table 4-14 summarizes the GIAFs used to estimate the ingestion intake from groundwater (Construction and Utility Workers only). Table 4-11 shows the exposure assumptions for ingestion exposure.

Ingestion Exposure Estimates

Tables 4-17 and 4-18a/b present the predicted exposure from ingestion for soil and groundwater (potable and subsurface contact), respectively.

4.2.3.4 Inhalation

Particulate

The exposure pathway related to the inhalation of fugitive dust derived from soil was evaluated to determine the need, if any, for dust control measures during future construction activities. This evaluation is also protective of exposure during current conditions in the absence of RMMs (that is, no paving or grass covers). The following equation was used to estimate exposure from dust inhalation (MECP, 2011b; Health Canada, 2010a):

$$DAD = \frac{C * PM_{10} * CF * IR_A * FPM_{inh} * EF1 * EF2 * EF3 * ED}{BW * AT} \quad (10)$$

Where:
DAD = Daily adsorbed or administered dose (mg/kg/d)

C = Chemical concentration in soil (mg/kg)

PM_{10} = Particulate concentration in air (µg-soil/m^3)

CF = Conversion factor, 1 kg/10^9 µg

IR_A = Inhalation rate (cubic metres per hour [m^3/hr])

FPM_{inh} = Fraction of particulate matter smaller than 10 microns in diameter (PM10) (unitless); MECP default value of 0.6 is applied herein

*EF*1 = Exposure frequency (days per week)

*EF*2 = Exposure frequency (weeks per year)

*EF*3 = Exposure frequency (hours per day)

ED = Exposure duration (years)

BW = Body weight (kg)

AT = Averaging time (lifetime or ED in years × 365 days per year)

As discussed in Section 4.1.2.1, the COCs in soil identified for quantitative assessment (that is, estimated maximum concentrations were greater than the MECP S1 component value) have been considered COCs for dust modelling in the HHRA.

Table 4-12 summarizes the receptors, receptor characteristics, and exposure assumptions used to model the dust inhalation pathway. Table 4-19 presents the predicted exposure from dust inhalation for the retained receptors.

Volatiles

For inhalation exposures, the amount of the chemical that reaches the target site is not a simple function of the inhalation rate and BW; therefore, intake equations developed based on these parameters are not recommended for estimating exposures to inhaled contaminants. Instead, an exposure concentration is calculated. The following equation was used to estimate exposure from inhalation of volatiles (MECP, 2011b; EPA, 2009):

$$EC = \frac{(C_{air} * EF1 * EF2 * EF3 * ED)}{AT} \quad (11)$$

Where:

EC = Exposure concentration (mg/m^3)

C_{air} = Volatile contaminant concentration in indoor or outdoor air (mg/m^3); this concentration is obtained through modelling, as described in Section 4.2.3.5 (indoor air) and Section 4.2.3.6 (outdoor air), and Appendixes G2 and G3

*EF*1 = Exposure frequency (days per week)

*EF*2 = Exposure frequency to indoor or outdoor air (weeks per year)

*EF*3 = Exposure frequency (hours per day)

ED = Exposure duration (years)

AT = Averaging time (hours)

The exposure concentration is then compared with the appropriate TRV to determine the level of risk.

Table 4-9 presents general receptor characteristics, such as exposure frequencies, EDs, and ATs, applied to the estimate of volatile COCs dose through the inhalation of indoor or outdoor air for all relevant receptors.

4.2.3.5 Soil and Groundwater to Indoor Air

The RA Property is anticipated to be redeveloped as mixed residential, parkland, and commercial. The Site currently consists of vacant land and all onsite buildings have been razed, with concrete floor slabs still in place. Future building plans for the property are unknown. Based on this information, indoor air exposure was modelled for generic residential and commercial building scenarios. For the residential building scenario, Residents are the maximally exposed receptors and for the residential building scenario, Indoor Workers represent the maximally exposed receptor to indoor air for the commercial building scenario. If exposure is determined to be acceptable, then all other receptors listed in Table 4-13 are considered protected. The onsite Site Visitor, Construction and Utility Workers were not retained for quantitative evaluation in this exposure assessment as it is not expected they would be exposed for any extended period within finished buildings.

Modelled Conditions

In September 1998, EPA developed a series of models to estimate indoor air concentrations and associated health risks from subsurface VI into buildings. These models were based on the analytical solutions of Johnson and Ettinger (J&E) (1991) for contaminant partitioning and subsurface vapour transport into buildings, and were updated in 2004.

For groundwater to indoor air evaluations, the depth to groundwater is used to determine whether the J&E model will be applied to calculate the Site-specific attenuation factor. The presence of contaminated groundwater less than 1.0 m away from a building's foundation precludes the use of the J&E Model for modelling VI from COCs in groundwater. In these cases, estimated indoor air concentrations are developed by applying the MECP's empirically derived attenuation values of 0.02 for a residential scenario and 0.004 for a commercial scenario (MECP, 2011b). Because groundwater elevations can fluctuate from spring to winter, the minimum depth to groundwater was used to account for seasonal variations in the water table to determine whether the MECP default attenuation factor or the J&E Model would be used for concentration calculations.

The calculated separation distance (refer to Table G2-2 in Appendix G2) between the foundation and the minimum depth to groundwater indicates the foundation is less than 1 m above the minimum depth to the water table for slab-on-grade foundations. Based on this, estimated indoor air concentrations for the groundwater-to-indoor-air pathway were derived using the MECP default residential and commercial attenuation factors for the generic residential and commercial building scenarios. J&E-modelled attenuation factors were used for the soil-to-indoor-air pathway for the identified building scenarios.

Appendix G2 presents the J&E input parameter table, as well as DATENTER and INTERCALCS worksheets from this assessment.

Indoor Air Vapour Estimates

Table 4-20 presents the predicted indoor air vapour concentrations from soil and groundwater for the generic residential and generic commercial scenarios.

Soil and groundwater–indoor air modelling was completed for the following scenarios:

- Generic Residential building
- Generic Commercial building

Estimated indoor air concentrations were developed through a two-step process. First, volatile partitioning relationships were applied to soil and groundwater data to produce estimated soil gas concentrations at the source. Second, MECP default and J&E-derived attenuation factors were applied to the soil gas concentrations to estimate indoor air concentrations.

These concentrations were used to derive an exposure concentration for each applicable receptor to be compared with the reference concentration (RfC) or unit risk (UR) (if the parameter was a carcinogen, see Section 4.3, Toxicity Assessment).

Spreadsheets indicating the development of the indoor air concentrations for the generic residential and commercial building scenarios are presented in Appendix G2. Calculations were performed using Microsoft Excel.

Tables 4-21a and 4-21b present the predicted exposure of receptors to COCs through the soil-to-indoor-air pathway for the generic commercial and residential building scenarios, respectively. Tables 4-22a and 4-22b

present the predicted exposure of receptors to COCs through the groundwater-to-indoor-air pathway for the commercial and residential building scenarios, respectively.

4.2.3.6 Soil and Groundwater to Outdoor Air Pathway (All Receptors)

Estimating exposure via this pathway involves calculating the predicted concentration of COCs in outdoor air because of the migration of vapours from subsurface soil layers and from groundwater through unsaturated soil into receptors' breathing spaces. The model described by Sanders and Stern (1994) was used to calculate the flux or emission rate of each individual COC at the boundary between the surface of the soil and ambient air. A box model (EPA, 1989) was then employed as a conservative dispersion model to calculate air concentrations of each predicted COC emission from the soil surface. Appendix G3 presents the model specifics, equations, and calculations used to estimate outdoor air concentrations.

For Construction and Utility Workers, it was assumed that the "box" could also be an excavated trench located within the subsurface. The enclosed nature of an excavated trench leads to decreased air exchange and increased soil surface area for fluxing; thus, results in increased potential exposure to subsurface volatiles via inhalation.

The RA Property is expected to undergo redevelopment in the future. The planned presence of paving and other surface materials will restrict the flow of soil gases and the migration of vapours, as concrete materials are much less porous than soil. However, for this exposure modelling, the presence of surface covers was conservatively ignored.

This assessment also employed the following conservative assumptions:

1) The degradation of COCs in the soil vadose zone was not considered if half-lives were not available.
2) The bulk water flow and infiltration of precipitation were ignored, as both of these would tend to retard the migration of vapours upward; therefore, would predict lesser concentrations.

Using the phase partitioning methods described in *Rationale for the Development and Application of Generic Soil, Groundwater and Sediment Criteria for Use at Contaminated Sites in Ontario* (MECP, 1996), COCs in groundwater were used to derive a "total" concentration, including:

- Concentration of a substance in soil gas phase (air)
- Soil water phase (dissolved)
- Soil particle phase (absorbed)

For this assessment, the predicted total concentration in soil based on the groundwater concentration was compared to the estimated maximum concentration in soil, and the greater of these two concentrations was applied to model volatilization to outdoor air. Tables 4-1 and 4-2 summarize the estimated maximum concentrations of volatile COCs in soil and groundwater, respectively.

Table 4-23 shows the predicted outdoor air concentrations (at ground surface and in a trench) determined as a result of the outdoor air calculations.

The receptors identified may be exposed to COCs volatilizing from soil and groundwater into outdoor air. Residents and Outdoor Workers are only exposed at the surface, whereas Construction Workers and Utility Workers would be maximally exposed in an excavation. The estimated dose for each receptor was calculated based on receptor characteristics and was compared with the RfC or UR (if the parameter was a carcinogen, see Section 4.3, Toxicity Assessment), which implies exposure at that concentration would be continuous over the receptors' lifetime (that is, 24 hours a day, 7 days a week, 52 weeks a year for a lifetime).

Table 4-24 presents the predicted exposure to subsurface volatiles in outdoor air for Residents and Workers above ground surface. Table 4-25 presents the predicted exposure to subsurface volatiles in outdoor air for Construction Workers and Utility Workers during time spent in a trench.

4.2.3.7 Exposure Estimates for Pregnant Adult Female Receptor

To assess the potential risk of exposure to developmental toxicants, an adult female receptor was assumed to be exposed continuously, to estimate exposure during Resident, Construction, Outdoor, and Utility[4]; and Indoor Worker scenarios.

The RA identified the following COCs as developmental toxicants:

- Lead
- B[a]P
- TCE
- Vanadium

4.2.4 Uncertainties—Exposure Assessment

Uncertainty exists in the RA's exposure assessment. Onsite receptors were hypothesized and activities assumed to result in exposures. Taken together, Jacobs developed the assumptions to be conservative and likely overestimate the potential exposure and risk:

- The screening process for volatility (Appendix F2) assumes that a chemical is volatile if the H is greater than 1×10^{-5} atm-m^3/mol or the vapour pressure is greater than 1.0 Torricelli (MECP, 2019). Slightly differing definitions of what constitutes a volatile chemical are available. Even if alternate screening criteria were applied and additional parameters identified as volatile, it is not expected to alter the conclusions of the RA.
- Exposure duration and frequencies for workers were assumed to occur on a regular and long-term basis, despite the reasonable potential that receptors may relocate, may change employment and job descriptions, and are unlikely to contact chemicals on a routine basis. The conservative way receptors have been identified and activities evaluated indicates uncertainties in the exposure assessment most likely allow for an overestimate of exposure, which will lead to an overestimation of risk.
- Exposure duration and frequency of exposure for Residents were assumed to occur on a regular and long-term basis (assumed the person would reside on the RA Property approximately 24 hours per day, 7 days per week, 50 weeks per year for a lifetime), despite the reasonable potential that receptors may move during their lifetime. The conservative way receptors have been identified and activities evaluated indicates uncertainties in the exposure assessment most likely allow for an overestimate of exposure, which will lead to an overestimation of risk.
- The exposure assessment section also defines the concentrations to which potential receptors may be exposed. Within the RA Property boundaries, vapour concentrations have been estimated using conservative models that incorporate general fate and transport factors intended to conservatively overestimate vapour concentrations to which exposures might occur. This conservative approach likely results in an overestimate of exposure and associated risk to certain receptors. These assumptions impart uncertainty to the RA but are purposely developed to verify that the RA conclusions are, indeed, conservative and protective of human health. Though the use of some assumptions may result

[4] The exposure assumptions for the Pregnant Female Construction, Outdoor, and Utility Worker are identical for all scenarios except dust inhalation; and the TRVs do not differ for the developmental toxicants identified in this RA (that is, the identified chronic and subchronic TRVs are the same). Therefore, these three receptors have been combined into one column in the exposure and risk tables as "Female Construction, Outdoor, or Utility Worker", where appropriate.

in lowering exposure and risk, the net effect of these uncertainties is that risk to potential receptors has likely been overestimated.

- In the assessment of indoor air, the use of soil concentrations and partitioning calculations to determine soil gas concentrations is not generally accepted for use in evaluating VI because there is a great degree of uncertainty associated with the soil partitioning results (EPA, 2002b), which could lead to over- or underestimating risk.
- Potential vapour concentrations in outdoor air were modelled assuming that receptors were chronically occupying the area of the RA property with the estimated maximum soil and groundwater concentrations. This assumption is conservative; therefore, the predicted exposure to COCs through outdoor air inhalation has likely been overestimated, which will lead to an overestimation of risk.
- Concentrations of contaminants are not uniformly distributed across the RA Property. The estimated maximum values for chemicals in soil and groundwater were used in the modelling. These concentrations appear in localized areas onsite and represent the greatest concentration based on judgmental sampling. Receptors would not consistently be exposed to the maximum concentration present at a site over their ED; therefore, the predicted exposure and risks have likely been overestimated.
- Potential vapour concentrations inside future RA Property buildings were modelled assuming the buildings are occupied and lie directly over the estimated maximum soil and groundwater concentrations detected at the RA Property (only for volatile COCs). This assumption is conservative; therefore, the predicted exposure to COCs through indoor air inhalation has likely been overestimated, which will lead to an overestimation of risk.
- The selected incidental ingestion rates for soil and groundwater may be different than the experimental basis used to develop them (for example, Construction and Utility Worker incidental ingestion of groundwater is based on exposure while swimming and nonincidental contact while working). Changes in ingestion rate would increase or decrease the predicted exposure and risk.
- The daily dermal events and ingestion exposures were hypothesized to have occurred on the RA Property. Some receptors may spend more time in a day not at the RA Property; therefore, these exposures from soil and groundwater have likely been overestimated. This will lead to an overestimation of risk.
- The assessment of exposure to PHC fraction (F)1, F2, F3, and F4 in soil and groundwater was conducted through application of subfraction proportions outlined in *Canada-Wide Standard for Petroleum Hydrocarbons (PHC) in Soil* (CCME, 2008) and *Federal Contaminated Site Risk Assessment in Canada, Part IV* (Health Canada, 2008). These proportions were specifically developed for soil and groundwater; however, Site-specific subfractions proportions may be different. The application of these proportions in the assessment of exposure to PHC in soil and groundwater adds uncertainty to the assessment and could lead to an overestimation or underestimation of exposure and risk to any subfraction grouping.
- The toxicity, mobility, and bioavailability of metals and metalloids in soil generally depend on several soil factors, including the following: pH, redox potential, iron and manganese content, and calcium carbonate content. Interactions between these soil factors can increase or decrease the toxicity, mobility, and bioavailability of these chemicals; however, the extent of the effects is unknown.
- The biodegradation of parent compounds to VC in groundwater is affected by site-specific geochemical parameters (redox potential, pH, and such), microbial activity, and chemical-specific parameters. These parameters can increase or decrease the biodegradation of chlorinated ethylenes to VC. Therefore, adding 10 percent of the parent compounds' maximum concentrations to the maximum VC concentrations may over- or underestimate the exposure to, and risks from, VC at the RA Property.

- The calculation of B(a)PE did not include contributions from methylnaphthalene 2- (1-), naphthalene, or others. Although some evidence of carcinogenicity has been identified for these parameters, it has not been confirmed in all cases, or for all routes of exposure. Accepted TEFs have not been established for these parameters. The exclusion of these parameters from the B(a)PE calculation could lead to an underestimation of exposure to B(a)PE.
- The uptake of vapours through skin was not assessed quantitatively and was considered negligible, compared with exposure of vapours through inhalation. The exclusion of this pathway could lead to an underestimation of exposure and risk.
- Lead was identified as a developmental toxicant for direct contact exposures, but was not assessed quantitatively via the Pregnant Female receptor. The exclusion of this toxicant-receptor scenario could lead to an underestimation of exposure and risk for developmental effects.
- The exposure assessment assumes worker exposure to groundwater would be limited to the hands, since dewatering is a typical construction practice that limits the presence of groundwater in construction areas. Additional body parts, such as forearms, may occasionally be exposed to groundwater, if accidental splashing were to occur. This scenario would increase the potential exposure area; however, an increase in the exposure area is unlikely.
- The Utility Worker receptor represents a worker who would be involved in the maintenance, installation, or repair of subsurface utilities or tunnels at the RA Property. As such, the Utility Worker is anticipated to be onsite full-time for only a limited number of days per year (assumed to be 2 weeks), but could return to the RA Property each year for additional work. The assumption of 2 weeks per year could over- or underestimate exposure in the short-term, but is unlikely to significantly underestimate risk in the long-term.
- The J&E modelling assumes an infinite source and does not account for the degradation of or removal processes for constituents, potentially significantly overestimating indoor air concentrations for soil.

4.3 Toxicity Assessment

This section describes the types of adverse effects a substance can cause following different routes of exposure (for example, ingestion, inhalation, or dermal), and the nature and severity of such effects associated with various levels of exposure, where increased exposure leads to increased risk of adverse effect (that is, dose-response relationship).

4.3.1 Nature of Toxicity (Hazard Assessment)

Two broad categories of adverse effects are considered: (1) threshold effects and (2) nonthreshold effects. For the threshold effect category, a substance is not expected to cause risk of an adverse effect at less than a certain dose (that is, the threshold dose). For nonthreshold effects, it is assumed that a substance may cause an adverse effect at any dose greater than zero. The former category is usually associated with noncancer effects, and the latter category is generally associated with cancer effects.

Chemicals assumed to exhibit threshold-type dose-response relationships exhibit a no-observed-adverse-effect level (NOAEL). At less than this threshold of exposure, the risk of adverse effect is essentially zero. This threshold is the basis for a TRV called a reference dose (RfD), which incorporates the use of safety factors, uncertainty factors (UFs), modifying factors, or a combination thereof. The magnitude of a factor depends on the confidence in the data and study used to derive the NOAEL and to account for inter- and intraspecies differences, EDs, and overall data quality of available data and information. The factors can easily span several orders of magnitude. The analogous exposure limit for airborne chemicals is called an RfC.

Chemicals that exhibit a nonthreshold-type dose-response are assumed to have no adverse effect only when the exposure or dose is zero. This dose-response model is generally applied to genotoxics (affects genetic material in biological cells) and carcinogens (causes cancer). Mathematical modelling is usually required to extrapolate cancer risk from animal studies to hypothetical human exposures. For chemicals that exhibit nonthreshold-type hazards, slope factors (SFs) and URs are used to determine the incremental lifetime cancer risk (ILCR) from exposure.

Many chemicals exhibit both types of dose-response relationships, exhibiting different adverse-effect end-points. Some COCs that are the subject of this assessment are assumed to have shown both threshold and nonthreshold adverse effects.

The following definitions have been extracted from the EPA's Integrated Risk Information System (IRIS) documentation (EPA, 2016a,b):

- **Reference Concentration (RfC):** An estimate (with uncertainty spanning perhaps an order of magnitude) of a continuous inhalation exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. It can be derived from a NOAEL, lowest-observed-adverse-effect level (LOAEL), or benchmark concentration, with UFs generally applied to reflect limitations of the data used. This estimate is generally used in EPA's noncancer health assessments.
- **Reference Dose (RfD):** An estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. It can be derived from a NOAEL, LOAEL, or benchmark dose, with UFs generally applied to reflect limitations of the data used. This estimate is generally used in the EPA's noncancer health assessments.
- **Slope Factor (SF):** An upper bound, approximating a 95 percent confidence limit, on the increased cancer risk from a lifetime exposure to an agent. This estimate, usually expressed in units of proportion (of a population) affected per mg/kg/d, is generally reserved for use in the low-dose region of the dose-response relationship (that is, for exposures corresponding to risks less than 1 in 100).
- **Unit Risk (UR):** The upper-bound excess lifetime cancer risk estimated to result from continuous exposure to an agent at a concentration of 1 µg/L in water or 1 µg/m^3 in air. The interpretation of UR would be as follows: if UR = 1.5×10^{-6} µg/L, 1.5 excess tumours are expected to develop per 1,000,000 people if exposed daily for a lifetime to 1 µg of the chemical in 1 L of drinking water.

Chemical-specific toxicity profiles in Appendix H include a description of the hazard assessment indicating the potential adverse health effects from exposure to the COCs in this assessment.

4.3.2 Dose Response Assessment

The TRVs were obtained from regulatory agencies, including the MECP and EPA (IRIS). Other TRVs cited in the Rationale Document (MECP, 2011b), such as those developed by the California Environmental Protection Agency, Office of Environmental Health Hazard Assessment, the Agency for Toxic Substances and Disease Registry, the Netherlands National Institute of Public Health and Environmental Protection, or the World Health Organization, were also considered. TRVs were obtained from published toxicity databases. If a database did not have a published value, an alternate source was reviewed. The TRVs used from other credible jurisdictions (as listed) meet the requirements as set out in Section 4.3.2 of *Procedures for the Use of Risk Assessment under Part XV.1 of the Environmental Protection Act* (MECP, 2005).

Noncarcinogenic TRVs (that is, RfDs and RfCs) can be based on several different toxicological end-points, including systemic effects, developmental toxicity, neurotoxicity, and reproductive effects. Typically, the

most sensitive end-point is selected for the derivation of the TRV (that is, the end-point associated with the least of the available LOAELs). Thus, the noncarcinogenic TRVs can generally be considered protective of all toxicological end-points. Furthermore, because a UF is typically applied during the TRV derivation process to account for intraspecies differences, the noncarcinogenic TRVs can generally be considered protective of all receptors (that is, including sensitive subgroups within the human population). Taken together, the noncarcinogenic TRVs can be viewed as protective of all toxicological end-points and all receptors, including, for example, developmental toxicity and pregnant women.

Table 4-26 lists the TRVs used in this RA and also briefly describes the potential health effects on human receptors associated with their exposure to those contaminants. There is great confidence that the TRVs selected for this assessment are relevant and protective of human health. RfDs and RfCs used in this assessment are considered protective of the human population (including sensitive subgroups) at continuous exposure levels (that is, 24 hours per day, 7 days per week). The human receptors identified in the problem formulation are likely to have exposure that is less continuous (that is, 40-hour work week); therefore, the RA provides another layer of conservatism. Similarly, URs and SFs used herein were derived by their respective agencies to account for continuous exposure.

Where more than one TRV is presented in Table 4-26 for the same route and effect (that is, threshold or nonthreshold) the available TRVs were applied as follows:

- **Sub-chronic TRVs** - Where available, sub-chronic TRVs (RfD and RfC) were applied only to the Construction Worker receptor.
- **Vinyl Chloride** - Two sets of carcinogenic TRVs (SF and URF) were selected for vinyl chloride. The TRVs specific to "continuous lifetime exposure from birth" were applied to the Composite Resident receptor for residential exposures, while the TRVs specific to "continuous lifetime exposure during adulthood" were applied to the Indoor Worker, Construction Worker, and Utility Worker receptors for job-related exposures (as these receptors are assumed to be adults per Section 4.2.1).

Chemicals with RfD and RfC TRVs are considered to have "threshold-acting" characteristics, while those with SFs and URs are considered to exhibit carcinogenic or nonthreshold characteristics. Contaminants with both RfD and RfC and SF and UR TRVs have been identified by the reporting regulatory agency as a chemical that can exhibit both types of health effects.

Appendix H presents toxicity profiles, which include a description of the chemical, health effects, assessment of carcinogenicity, and basis of the selected TRV for the chemicals and TRVs not presented in the Rationale Document (MECP, 2011b) or in the updated TRVs provided by the MECP (Pagliarulo, 2017, pers. comm.; Blok, 2018, pers. comm).

For the assessment of Pregnant Female Workers, the following COCs were identified as developmental toxicants:

- Lead
- B[a]P
- TCE
- Vanadium

There are uncertainties associated with the available TRVs for lead, which may not consider the potential adverse health effects at blood lead levels (BLLs) less than the current Canadian BLL intervention level of 10 micrograms per decilitre (µg/dL). As a result, the RA has not quantitatively assessed exposure and risk to lead via the direct contact route. Lead has also been identified as a developmental toxicant, but risk was

not assessed quantitatively for the Pregnant Female receptor, as no TRV protective of developmental effects to a foetus are available.

4.3.3 Uncertainties—Toxicity Assessment

Without exception, the toxicity indices employed in this RA have been developed in a conservative fashion to facilitate the protection of human health, as follows:

- Indices, such as cancer SFs and noncancer RfDs, are intentionally developed to be protective of human health. Cancer SFs are developed assuming that a threshold for effects does not exist. RfDs are frequently derived using several UFs (ranging from 1 to 10) and modifying factors (ranging from 10 to 10,000) that, in effect, lessen the dose responsible for the toxic effects. Furthermore, additional modifying factors are applied, depending on the confidence level of the database used to derive a toxicity limit. If confidence is low (that is, because of limited information, variations within the test species populations, or differences between the test species and humans), the factor applied is relatively high and accounts for the lack of knowledge.
- Jacobs built in an additional consideration of uncertainty into this RA by including a separate developmental toxicity-based TRV evaluation for a Pregnant Female receptor exposure scenario.
- Jacobs evaluated PAHs for nonthreshold (carcinogenic) effects if they were identified to have carcinogenicity or genotoxicity, or both, as described by EPA, and International Programme on Chemical Safety (WHO, 1998) classifications for this group of chemicals. The aromatic PAHs were not identified as genotoxic or carcinogenic chemicals, do not have common mechanisms of action to cause toxicity as the carcinogenic PAHs, or do not have a well-established TEF. Therefore, Jacobs did not include them in its TEF approach for B(a)PE estimations; however, the uncertainty associated with the risk estimation for the B(a)PE is likely to be minimal.
- The evaluation of B(a)PE assumes that the toxicological endpoint for all identified carcinogenic PAHs are the same as B(a)P. This may result in an under or over estimation of potential risks associated with exposure to carcinogenic PAHs.
- The MECP uses route-to-route extrapolation to derive an RfC value, typically from RfD values for chemicals without readily published RfC values. Additionally, Jacobs conducted a literature search for RA Property COCs to identify published RfC values from other agency guidance documents. Table 4-26 lists the identified selected TRVs. However, some chemicals did not have RfC values because such chemicals are not an inhalation exposure concern, most likely due to low volatility or lack of toxicity through inhalation route of exposure. Thus, uncertainty associated with the absence of RfC or URF values for such chemicals is considered minimal.
- Over time, as more information from studies and research become available, toxicological information for constituents is updated. As a result, TRVs are expected to change over time. If TRVs are updated, changed, or added, they could inherently change the estimated risk.
- Due to uncertainties associated with the available TRVs for lead, which may not consider the potential adverse health effects at BLLs less than the current Canadian BLL intervention level of 10 µg/dL, Jacobs has not quantitatively assessed exposure and risk to lead via the direct contact or inhalation exposure routes in this RA. Lead has also been identified as a developmental toxicant but was not assessed quantitatively via the Pregnant Female receptor, as no TRV protective of developmental effects to a foetus is available.
- In the absence of TRVs developed specifically for intermittent exposures, Jacobs adopted chronic TRVs to assess risks to the Utility Worker. This may result in an under or over estimation of potential risks to this receptor.

4.4 Risk Characterization

4.4.1 Interpretation of Health Risks

The risk characterization stage integrates the results of the exposure assessment with the information obtained during the toxicity analysis. Jacobs derived risk estimates for noncarcinogens (threshold toxicity response) by comparing the exposure intake results to the TRVs.

A comparison of the estimated exposure and estimated air concentration for each chosen substance to the appropriate RfD and RfC, respectively, will provide an estimate of the potential health risk associated with each. If the modelled exposure or air concentrations are less than the appropriate RfD or RfC, adverse health impacts are not expected. The comparison estimates are as described by the following ratios:

$$Exposure\ Ratio = \frac{Predicted\ Exposure\ Rate}{Reference\ Dose\ (RfD)} \quad (12)$$

or

$$Exposure\ Ratio = \frac{Predicted\ Air\ Concentration}{Reference\ Concentration\ (RfC)} \quad (13)$$

Exposure ratios (ERs) are also referred to as hazard quotients (HQs). The MECP considers an ER or HQ of 0.2 to be acceptable for any one environmental medium, if multimedia exposure is possible (MECP, 2011b). The target HQ used in this assessment for all COCs except PHC and TCE (for inhalation only) was 0.2. The target HQ for PHC fractions and TCE (inhalation only) was 0.5 (CCME, 2008; MECP 2016b). MECP (2016b) guidance states that an HQ of 0.5 is acceptable for "TCE exposure inhalation of indoor air (and possibly also outdoor air)" because intake of TCE from other pathways (that is, ingestion in food, groundwater, and soil; and dermal contact with soil) is negligible in comparison (for non-potable sites). It is the QPRA's opinion that the HQ of 0.5 for TCE is also appropriate to apply to the outdoor air inhalation pathway because inhalation (in general terms) is the primary route of exposure to TCE where a potable groundwater use is not present. It is noted that the RA Property has a potable groundwater condition, and therefore, the use of the HQ of 0.5 would typically not be acceptable. However, while groundwater is considered potable in general, impacted groundwater at the Site is not used as a potable resource. RMMs are included in Section 7 to prevent potable water use from RA Property groundwater. As such, the use of the HQ of 0.5 for TCE (for inhalation pathways only) is considered appropriate for the assessment.

The MECP (2011b) HQ of 0.2 is equal to one-fifth of the applicable noncancer TRV. The RfD and RfC define either the exposure rate or concentration of chemical in air that humans, including sensitive individuals, may be exposed to over a lifetime without an appreciable risk of experiencing an adverse effect (which is equivalent to an HQ of 1.0 [EPA, 2000]). If HQs are shown to be greater than 1.0, this does not imply that an adverse effect will result, only that there is a potential for an adverse effect. Because of the conservative nature of the assumptions underlying the calculation of exposure and air concentrations, there is an inherent tendency to overpredict exposure. Furthermore, the scientific principles employed to derive RfD and RfC values are based on selecting the most sensitive end-point observed in the most sensitive gender of the most sensitive species and consider uncertainties in the toxicology assessment database. Overall, these TRVs are expected to be protective of human health.

UFs that span several orders of magnitude (for example, often 1,000-fold or greater) are placed on dose-response models in animal toxicity studies to protect human health. Often, the TRV is developed from the NOAEL in animal studies, which is a dose that does not cause harm to an animal. The greater the uncertainty

in the toxicological study, the larger the UF that is employed. Taken together, the overprediction of exposure and the minimization of the toxicity value provide a comprehensive approach to the protection of human health and the environment.

Estimates of risk for carcinogens (nonthreshold response) are derived by the following relationship, where the ILCR is calculated:

$$ILCR = Exposure\ Estimate \times Cancer\ SF \quad (14)$$

or

$$ILCR = Exposure\ Concentration \times UR \quad (15)$$

For the ILCR, values between 1×10^{-6} and 1×10^{-4} are typically considered to be a negligible increase of risk. The MECP has selected a target ILCR of 1×10^{-6} (1 in 1 million) as the acceptable level of risk, which was used in this assessment.

Based on the hazard assessment, some COCs may act toxicologically the same or in a similar manner on biological systems (that is, carcinogenic PAHs or chlorinated volatile organic compounds [cVOCs]). For this RA, Jacobs calculated the cumulative risk for PAHs in soil and groundwater and cVOCs in groundwater to conservatively address the potential for exposure to these groups of substances.

4.4.2 Quantitative Interpretation of Health Risks

4.4.2.1 Dermal Contact with Soil

Table 4-27 shows the predicted risks from dermal contact with soil. Risks to Site Visitors and Indoor Workers were indirectly assessed through the modelling for onsite Residents and Outdoor Workers, respectively (refer to Section 4.4.3.1). Risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Resident	• B(a)P • Copper • Iron • Zinc • PHC F3	• Arsenic • Benzo(a)anthracene • B(a)P • Benzo(b)fluoranthene • Benzo(k)fluoranthene • Dibenzo(a,h)anthracene • Fluoranthene • Indeno(1,2,3-Cd)Pyrene • B(a)PE
Outdoor Worker	• B(a)P	• Arsenic • Benzo(a)anthracene • B(a)P • Benzo(b)fluoranthene • Benzo(k)fluoranthene • Dibenzo(a,h)anthracene • Fluoranthene • Indeno(1,2,3-Cd)Pyrene • B(a)PE
Construction Worker	• None	• B(a)P • B(a)PE

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Utility Worker	• None	• Arsenic • B(a)P • B(a)PE
Pregnant Female Resident	• B(a)P	• Not applicable
Pregnant Female Worker (Outdoor, Construction, or Utility)	• None	• Not applicable

Based on the assessment of risks from dermal contact with soil, risks greater than the target cancer risk are possible. RMMs are, therefore, required to reduce the potential risks to acceptable levels. Jacobs did not conduct a quantitative assessment of lead in soil; Section 4.4.3.5 provides the qualitative assessment.

4.4.2.2 Dermal Contact with Groundwater

Table 4-28a shows the predicted risks from Resident dermal contact with groundwater as potable drinking water. Table 4-28b shows the predicted risk from Construction and Utility Worker dermal contact with groundwater while working in the subsurface. Risks to Site Visitors and Indoor Workers were indirectly assessed through the modelling for onsite Residents (refer to Section 4.4.3.1). Risks to offsite receptors (that is, offsite Construction and Utility Workers) were indirectly assessed through the modelling for onsite Construction and Utility Workers (refer to Section 4.4.3.2).

For potable groundwater, risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Resident	• 2-(1-)Methylnaphthalene • Benzene • B(a)P • Cis-1,2-dichloroethene • Fluoranthene • Phenanthrene • Pyrene • TCE • VC • PHC F2 • PHC F3	• Acenaphthene • Arsenic • Benzene • Benzo(a)anthracene • B(a)P • Benzo(b+j)fluoranthene • Benzo(k)fluoranthene • Chrysene • Fluoranthene • Pyrene • TCE • VC • B(a)PE
Pregnant Female Resident	• B(a)P • TCE	• Not applicable

For incidental contact with groundwater, risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Construction Worker	• TCE • PHC F2 • PHC F3	• B(a)P • TCE VC • B(a)PE
Utility Worker	• PHC F2 • PHC F3	• B(a)P

		• TCE VC • B(a)PE
Pregnant Female Worker (Construction or Utility)	• TCE	• Not applicable

Based on the assessment of risks from dermal contact with groundwater (drinking water and incidental), risks greater than the target cancer risk are possible. RMMs are, therefore, required to reduce the potential risks to acceptable levels. Jacobs did not conduct a quantitative assessment of lead in groundwater; Section 4.4.3.5 provides the qualitative assessment.

4.4.2.3 Uncertainties—Dermal Contact

Uncertainties related to the estimation of dermal exposure and risk are as follows:

- The relative DAF and SAFs may be different than the experimental basis used to develop them. This may over- or underestimate the risk.
- The model does not account for the removal of soil contaminants from the receptors' hands by brushing off or washing them off. This may overestimate the risk from exposure.
- Concentrations of contaminants are not distributed uniformly across the RA Property. The estimated maximum detected values for chemicals in soil and groundwater were used in the modelling. These concentrations may appear in localized areas on the RA Property and represent the greatest concentration based on judgmental sampling. Receptors would not consistently be exposed to the maximum concentration present at a site over their lifetime; therefore, the predicted risks have likely been overestimated.
- Site users were assumed to have access to the maximum detected concentrations of chemicals (regardless of depth) on an ongoing and constant basis. Under normal circumstances, only a Construction or Utility Worker would have access to soil located at depths impacted with COCs at maximum detected concentrations.
- The exposure assessment assumes worker exposure to groundwater would be limited to the hands. Additional body parts, such as forearms, may occasionally be exposed to groundwater, increasing potential exposure area; however, a significant increase in the exposure area is unlikely.
- The likelihood is low that Construction or Utility Workers would have their hands submerged continuously in groundwater even for one 5-minute event per day for the duration of the construction period. Typical construction activities include the dewatering of excavations. Therefore, it is unlikely that these receptors would have significant exposure to groundwater when using typical construction practices.
- The K_p used in this RA has uncertainty and could overestimate exposure for highly lipophilic compounds and underestimate exposure from other organic compounds, such as chlorinated compounds. The risk estimates could be higher or lower. Peer-reviewed estimates of chemical physical properties were used where available.

4.4.2.4 Incidental Ingestion of Soil

Table 4-29 shows the predicted risks from incidental ingestion of soil. Risks to Site Visitors and Indoor Workers were indirectly assessed through the modelling for onsite Residents and Outdoor Workers, respectively (refer to Section 4.4.3.1). Risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Resident	• Arsenic • B(a)P • Cadmium • Cobalt • Copper • Iron • PCB, Total • Thallium • TCE • Vanadium • Zinc • PHC F3	• Arsenic • Benzo(a)anthracene • B(a)P • Benzo(b)fluoranthene • Benzo(k)fluoranthene • Chrysene • Dibenzo(a,h)anthracene • Fluoranthene • Indeno(1,2,3-cd)pyrene • TCE • B(a)PE
Outdoor Worker	• B(a)P • Cadmium • Cobalt • Thallium	• Arsenic • Benzo(a)anthracene • B(a)P • Benzo(b)fluoranthene • Benzo(k)fluoranthene • Chrysene • Dibenzo(a,h)anthracene • Fluoranthene • Indeno(1,2,3-cd)pyrene • B(a)PE
Construction Worker	• Cadmium	• Arsenic • B(a)P • B(a)PE
Utility Worker	• None	• Arsenic • B(a)P • B(a)PE
Pregnant Female Resident	• B(a)P •	• Not applicable
Pregnant Female Worker (Outdoor, Construction, or Utility)	• None	• Not applicable

Based on the assessment of risks from incidental ingestion of soil, risks greater than the target cancer and noncancer risks are possible. RMMs are, therefore, required to reduce the potential risks to acceptable levels. Jacobs did not conduct a quantitative assessment of lead in soil; Section 4.4.3.5 provides the qualitative assessment.

4.4.2.5 Ingestion of Groundwater

Table 4-30a shows the predicted risks from Resident ingestion of RA Property groundwater as potable drinking water. Table 4-30b shows the predicted risks from Construction and Utility Worker incidental ingestion of groundwater while working in the subsurface. Risks to Site Visitors and Indoor Workers were indirectly assessed through the modelling for onsite Residents (refer to Section 4.4.3.1). Risks to offsite receptors (that is, offsite Construction and Utility Workers) were indirectly assessed through the modelling for onsite Construction and Utility Workers (Section 4.4.3.2).

For potable water, risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Resident	• 2-(1-)Methylnaphthalene • Arsenic • Benzene • B(a)P • Cis-1,2-dichloroethene • Phenanthrene • Trans-1,2-dichloroethene • TCE • Zinc • VC • PHC F2 • PHC F3 • PHC F4	• 1,1-dichloroethane • Acenaphthene • Arsenic • Benzene • Benzo(a)anthracene • B(a)P • Benzo(b+j)fluoranthene • Benzo(k)fluoranthene • Chrysene • Fluoranthene • Pyrene • TCE • VC • B(a)PE
Pregnant Female Resident	• B(a)P • TCE •	• Not applicable

For incidental ingestion, risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Construction Worker	• TCE • PHC F2 • PHC F3	• Arsenic • TCE • VC
Utility Worker	• TCE • PHC F3	• Arsenic • TCE • VC
Pregnant Female Worker (Construction or Utility)	• TCE	• Not applicable

Based on the assessment of risks from ingestion of groundwater (drinking water and incidental), risks greater than the target cancer and noncancer risks are possible. RMMs are, therefore, required to reduce the potential risks to acceptable levels. Jacobs did not conduct a quantitative assessment of lead in groundwater; Section 4.4.3.5 provides the qualitative assessment.

4.4.2.6 Uncertainties—Ingestion

Uncertainties related to the estimation of ingestion exposure and risk are as follows:

- The amount of water assumed to be ingested by Construction and Utility Workers in this assessment is equivalent to the amount considered to be ingested during swimming activities (50 millilitres [mL], based on EPA [1989]). The actual ingestion of groundwater is likely to be insignificant. The assumption will likely overestimate the risk to Construction and Utility Workers.

- Typical construction activities include dewatering excavations; therefore, it is unlikely that Construction or Utility Workers will be exposed to groundwater. Less exposure will result in lesser risk estimates.
- Concentrations of contaminants are not uniformly distributed across the RA Property. The estimated maximum detected values for chemicals in soil and groundwater were used in the modelling. These concentrations appear in localized areas on the RA Property and represent the greatest concentration based on judgmental sampling. Receptors would not consistently be exposed to the maximum concentration present at a site over their lifetime; therefore, the predicted risks have likely been overestimated.
- Site users were assumed to have access to the maximum detected concentrations of chemicals (regardless of depth) on an ongoing and constant basis. Under normal circumstances, only a Construction or Utility Worker may have access to soil or groundwater deep enough to be impacted with COCs at maximum detected concentrations.
- The incidental ingestion rates may be different than the experimental basis used to develop them. Changes in ingestion rate would increase or decrease the predicted risk.

4.4.2.7 Summary of Direct Contact (Dermal and Ingestion) with Soil

Table 4-31 shows the calculated combined risk from dermal contact and ingestion with soil. Adding the two exposure pathways resulted in the addition of the following COCs and receptors with risks greater than MECP target levels:

- Phenanthrene, PHC F2, and PHC F4 exceed the target noncancer risk for the Toddler Resident
- TCE exceeds the target cancer risk and copper and iron exceed the noncancer risk for the Outdoor Worker.
- Benzo(b)fluoranthene and dibenzo(a,h)anthracene exceed the target cancer risk for the Utility Worker.
- Copper, iron, and zinc exceed the target noncancer risk for the Construction Worker.

Risks associated with dust were not included in Table 4-31. This is because the risks associated with dust inhalation are minor compared to the dermal or ingestion pathways. While there is uncertainty associated with excluding dust from these tables, its inclusion does not affect the conclusions of the assessment or the RMMs required for the RA Property. Section 4.4.3.8 provides a qualitative assessment of inhaled soil particulates that are ingested.

4.4.2.8 Summary of Direct Contact (Dermal and Ingestion) with Groundwater

Tables 4-32a and 4-32b show the calculated combined risk from dermal contact and ingestion with groundwater for the RA Property for potable water by Residents and subsurface contact by Workers, respectively. Adding the two exposure pathways resulted in the addition of the following COCs and receptors with risks greater than MECP target levels:

- Fluoranthene exceeds the target noncancer risk for the Infant Resident
- Trans-1,2-dichloroethene exceeds the target noncancer risk for the Child Resident.
- Phenanthrene and pyrene exceed the target noncancer risk for the Adult Resident.

4.4.2.9 Inhalation of Fugitive Dust

Table 4-33 shows the predicted risks from inhalation of particulates (dust) originating from RA Property soil both during construction activities and following redevelopment. Risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Resident	• None	• None
Outdoor Worker	• None	• None
Construction Worker	• B(a)P • Cobalt • Zinc	• None
Utility Worker	• None	• None
Pregnant Female Resident	• None	• Not applicable
Pregnant Female Worker (Outdoor)	• None	• Not applicable
Pregnant Female Worker (Construction or Utility)	• B(a)P	• Not applicable

Based on the assessment of risks from inhalation of particulates (dust), risks greater than the target noncancer risks are possible for pregnant subsurface workers during construction activities. RMMs are, therefore, required during construction activities to reduce the potential risks to acceptable levels.

It was not possible to quantitatively assess lead or iron for the dust inhalation pathway due to a lack of toxicity criteria for these parameters. For these COCs, the background soil values are considered appropriate to determine whether concentrations at the RA Property may pose a greater risk to human health than that expected at an Ontario property that has not been impacted by anthropogenic activities (refer to Section 4.4.3.5 for a qualitative analysis). Based on the qualitative analysis of lead and iron, RMMs are also required to reduce the potential risks from exposure to these COCs to acceptable levels.

4.4.2.10 Uncertainties—Dust Inhalation

Uncertainties related to the estimation of dust inhalation exposure and risk are as follows:

- Inhalation RfDs and URs were derived from RfCs and URFs using a default inhalation rate of 20 cubic metres per day (m^3/d) and a BW of 70 kg to assess risks from dust inhalation as a dose. This conversion is specific to adults; therefore, risks from dust inhalation may be underestimated for nonadult receptors. However, since an elevated risk is already estimated for the pathway, the conclusion that RMMs are required is not affected by this uncertainty.
- Risk to offsite receptors would likely be less than experienced by Site users, since the concentration of COC-impacted fugitive dusts diminishes rapidly with dispersion and dilution in air and with distance (EPA, 2002a).
- The total dust in the air is highly variable; as a result of the uncertainty in the dust concentrations, Jacobs used a conservative value, likely resulting in an overestimate of exposure and risk.
- A suitable noncancer TRV for inhalation of lead and iron are not currently available; therefore, Jacobs could not estimate the noncancer inhalation risks from lead and iron in dust. As RMMs are required for this pathway for other COCs, the potential for noncancer risks greater than MECP targets from lead in dust will be managed as part of the RMP.

4.4.2.11 Inhalation of Indoor Air

Tables 4-34a and 4-34b show the predicted risks from inhalation of vapours migrating from soil to indoor air for all retained receptors under commercial building and residential building scenarios, respectively.

For the generic commercial building soil to indoor air scenario, risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Indoor Worker	• Benzene • Naphthalene • TCE • PHC F2	• Benzene • TCE
Pregnant Female Indoor Worker	• TCE	• Not applicable

For the generic residential building soil to indoor air scenario, risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Resident	• Benzene • Mercury • Naphthalene • PHC F2 • TCE • Xylenes, total	• Acenaphthene • Benzene • TCE
Pregnant Female Resident	• TCE	• Not applicable

Tables 4-35a and 4-35b show the predicted risks from inhalation of vapours migrating from groundwater to indoor air for all retained receptors under commercial building and residential building scenarios, respectively.

For the generic commercial building groundwater to indoor air scenario, risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Indoor Worker	• Benzene • 1,1-dichloroethene • Cis-1,2-dichloroethene • Trans-1,2-dichlorothene • n-hexane • TCE • VC • PHC F1 • PHC F2	• Benzene • 1,1-dichloroethane • TCE • VC

Pregnant Female Indoor Worker	• TCE	• Not applicable

For the generic residential building groundwater to indoor air scenario, risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Resident	• Benzene • 1,1-dichloroethane • 1,1-dichloroethene • Cis-1,2-dichloroethene • Trans-1,2-dichlorothene • n-hexane • (2-)1-Methylnaphthalene • Naphthalene • Tetrachloroethylene • 1,1,1-trichloroethane • TCE • VC • PHC F1 • PHC F2	• Acenaphthene • Benzene • 1,1-Dichloroethane • Tetrachloroethylene • TCE • VC
Pregnant Female Resident	• TCE	• Not applicable

Based on the assessment of risks from inhalation of vapours in indoor air originating from soil and groundwater for the modelled building scenarios, unacceptable risks are possible for the generic commercial and residential building scenarios. RMMs are, therefore, required to reduce the potential risks to acceptable levels for the generic commercial and residential building scenarios.

4.4.2.12 Uncertainties—Indoor Air

Uncertainties related to the estimation of inhalation exposure and risk are as follows:

- The degradation of organic compounds along the transport path was ignored. If degradation was included, the chemical concentration would decrease, which would decrease the estimated risks.
- For indoor air assessments, it is not generally acceptable to use soil concentrations and partitioning calculations to determine soil gas concentrations while evaluating VI because there is a great degree of uncertainty associated with the soil-partitioning results (EPA, 2002b), which could lead to over- or underestimating risk.
- The exposure assessment section also defines the concentrations of COCs to which potential receptors may be exposed. Within the RA Property boundaries, Jacobs estimated potential indoor air vapour concentrations by using conservative models that incorporate general fate and transport factors intended to conservatively overestimate vapour concentrations to which a receptor might be exposed. The selection of conservative assumptions regarding Site-specific inputs may result in an overestimate of exposure and associated risk to certain receptors. These assumptions all impart uncertainty to the

RA but are purposely developed to yield RA conclusions that are, indeed, conservative and protective of human health.

- Vapour concentrations inside future RA Property buildings were modelled assuming the buildings are occupied, and the VI pathway is complete, meaning soil vapours can enter the structure. This assumption is conservative because the exposure pathway may not actually be complete or significant; therefore, there may be no or little associated risk.
- Exposure modelling for indoor air conservatively assumes the structure lies directly over the estimated maximum soil and groundwater concentrations for volatile COCs detected at the RA Property. It is also assumed that the source is infinite, and the modelling does not account for degradation of constituents. These factors may significantly overestimate indoor air concentrations and risk.
- A source of uncertainty in indoor air vapour concentration model results is the use of partitioning coefficients from other media into soil vapour to predict subslab soil vapour concentrations of COCs and, in turn, to assess potential indoor air concentrations. Modelling results based on ideal chemical properties of the COCs may not appropriately represent true portioning between media that occurs on a site-specific basis. This results in uncertainty in the model results that could over- or underestimate risk.

4.4.2.13 Inhalation of Outdoor Air Volatiles

Table 4-36 shows the predicted risk for Residents and Workers from inhalation of subsurface volatiles migrating to outdoor air above the ground surface at the RA Property. Risks to each receptor were estimated to be less than the MECP target noncancer and cancer risks for the retained COCs. RMMs are, therefore, not required at the RA Property to reduce the potential risks to acceptable levels. Risks to onsite Indoor Workers and offsite receptors (that is, offsite Surface Receptors, and Construction and Utility Workers) were indirectly assessed through the modelling for onsite Residents and Workers (Sections 4.4.3.1 and 4.4.3.2).

Table 4-37 shows the predicted risk for Utility and Construction Workers from inhalation of subsurface volatiles migrating to outdoor air in an excavated trench for the RA Property. Risks were estimated to exceed the MECP target risks as follows:

Receptor	Exceeds MECP Target Noncancer Risk	Exceeds MECP Target Cancer Risk
Construction Worker	• Naphthalene • TCE • PHC F2	• None
Utility Worker	• None	• None
Pregnant Female Worker (Construction or Utility)	• TCE	• Not applicable

RMMs are required during excavation activities at the RA Property to reduce the potential risks to acceptable levels.

Table 4-38 shows the combined predicted risk for Utility and Construction Workers from the inhalation of subsurface volatiles migrating to outdoor air above ground surface and in an excavated trench. Adding the two pathways did not result in any COCs exceeding the MECP target risk levels for any receptor.

4.4.2.14 Uncertainties—Outdoor Air Volatiles Inhalation

Uncertainties related to the estimation of outdoor air inhalation exposure and risk are as follows:

- The comparators used to predict risk (that is, RfC and UR) are values considered protective of lifetime exposure to chemicals—24 hours per day, 7 days per week, 52 weeks per year, for 70 years—and include adjustments for sensitive individuals in the human population. Therefore, for any human receptor, risks are overestimated for short-term exposure to volatile chemicals that may be present in air, since no person will occupy the RA Property for a duration consistent with the duration used to develop the comparators. Adjustment of the comparator for shortened duration would likely result in a decreased risk for receptors.
- Risk to offsite receptors, included Residents, would likely be less than experienced by Site users, since the concentration of volatile COCs in air diminishes with dispersion and dilution in air rapidly with distance (EPA, 2002a).
- As outline in Appendix G3, outdoor air concentrations in a trench have been modelled based on an assumed wind speed and the assumed presence of a worker in a trench. Actual concentrations may be under- or overestimated. However, typical practices for trench excavation prohibit entry because the trench is considered a confined space. Therefore, exposure estimates are likely to overestimate risks in this case.

4.4.3 Qualitative Interpretation of Health Risks

This section discusses parameters and exposure scenarios that were qualitatively assessed in the HHRA.

4.4.3.1 Qualitative Assessment of Additional Onsite Receptors

Site Visitors of all ages may also be present at the RA Property under future conditions. These receptors may also be exposed to RA Property impacts; however, their exposure will be less than that of the receptors included for quantitative assessment. Similarly, Indoor Workers were not included for quantitative assessment for pathways other than indoor air inhalation, because they have less exposure to outdoor air and direct contact with Site soils relative to a full-time Outdoor Worker. It is understood that if risks to the quantitatively evaluated receptors are identified, risks to these onsite receptors are also possible through relevant exposure pathways.

The following risk conclusions have been made for quantitatively evaluated receptors and are understood to possibly exist for the qualitatively evaluated onsite receptors:

- Unacceptable risks from direct contact with soil are possible for Indoor Workers, Site Visitors, and for non-Toddler Residents (infant, child, teen, and adult).
- Unacceptable risks from incidental ingestion of soil are possible for Indoor Workers, Site Visitors, and non-Toddler Residents (infant, child, teen, and adult).
- Unacceptable risks from ingestion of groundwater as potable water are possible for Indoor Workers and ingestion of drinking water for Site Visitors and non-Toddler Residents (infant, child, teen, and adult) and Indoor Workers.
- Unacceptable risks from inhalation of volatiles in outdoor air above ground are not expected for Indoor Workers, Site Visitors, and non-Toddler Residents (infant, child, teen, and adult).
- Unacceptable risks from dust inhalation are possible for non-Toddler Residents, Site Visitors, and Indoor Workers from lead and iron.

4.4.3.2 Qualitative Assessment of Offsite Receptors

Offsite receptors may also be exposed to Site media if impacted soil particulates, vapours, or groundwater migrates beyond the RA Property boundaries; however, their exposure will be less than that of the onsite receptors included for quantitative assessment. If risks to the quantitatively evaluated onsite receptors are identified, then risks to these offsite receptors are also possible through relevant exposure pathways.

The following risk conclusions have been made for quantitatively evaluated onsite receptors (Section 4.4.2) and are understood to possibly exist for the qualitatively evaluated offsite receptors should offsite migration of dust (from onsite soils) or groundwater occur:

- Unacceptable risks from dust inhalation are possible for offsite Surface Receptors from lead and iron, offsite Construction and Utility Workers from B(a)P, cobalt, zinc, B(a)P, and lead and iron; and offsite Female Construction and Utility Workers from B(a)P.
- Unacceptable risks from dermal contact or incidental ingestion of groundwater are possible for offsite Construction and Utility Workers.
- Unacceptable risks from dermal contact or ingestion of groundwater as potable drinking water are possible for offsite Surface Receptors.
- Unacceptable risks from inhalation of volatiles from soil or groundwater to indoor air are possible for offsite Surface Receptors in residential or industrial/commercial buildings. The following bullets provide additional interpretation:
  - Residential receptors are not present directly to the south or east, closest to where the highest concentrations of volatile COCs in soil have been detected.
  - Per the updated draft MECP document entitled *Technical Guidance for Soil Vapour Intrusion Assessment* (MECP 2021) "soil vapour migration tends to be insignificant at distances of approximately 30 m from the edge of the subsurface contamination" for recalcitrant chemicals, and approximately 10 m for readily-biodegradable chemicals such as PHCs and BTEX. .
  - Considering the distances cited by the MECP (2021) and using the generic S-IA components for an offsite ICC land use, the Site soil data was further evaluated for potential issues to offsite commercial buildings (no residences are located within 30 m of a location with a volatiles exceedance). Per Table 3-34a, onsite risks to occupants of commercial buildings were predicted to be greater than MECP target risk values only for benzene, naphthalene, TCE, and PHC F2 in soil. Therefore, these COCs were examined further, as follows:
    - All concentrations of benzene in soil onsite are less than the Table 2 ICC S-IA component value. Risk from lateral gas movement offsite of benzene from onsite soil sources is unlikely.
    - One soil location has concentrations of naphthalene greater than the Table 2 ICC S-IA component (OW07-34D), located approximately 26 m from the southern property boundary. Risk from lateral gas movement offsite of naphthalene from onsite soil sources is unlikely to low based on a single exceedance of the S-IA component and distance of this location to the property boundary.
    - Twelve locations have TCE concentrations in soil greater than the generic Table 6 SCS[5], all locations are within the northeast corner of the Site within 16 m of the property boundary, co-located with highest TCE impacts in groundwater. Risk from lateral gas movement offsite of TCE from onsite soil sources is possible, based on the proximity to the property boundary. However, considering the associated groundwater concentrations in this area, the primary

[5] The Table 2 ICC S-IA component is less than background; therefore, the generic Table 6 SCS was used.

source of potential TCE vapours in this corner are associated with groundwater. RMMs are proposed to mitigate risks to receptors in offsite buildings from offsite groundwater migration.

- One soil location has concentrations of PHC F2 greater than the Table 2 S-IA component (BH07-40), located approximately 25 m from the eastern property boundary. Risk from lateral gas movement offsite of PHC F2 from onsite soil sources is unlikely to low based on a single exceedance of the S-IA component and the distance of this location to the property boundary.

– Based on this evaluation, the potential for risk from lateral soil gas movement offsite of benzene, naphthalene, and PHC F2 from onsite soil sources is considered unlikely to low.

– Soil gas concentrations typically decrease rapidly with distance from the source due to various processes (such as degradation and adsorption); therefore, soil gas generated from impacted soil onsite is less likely to pose a risk to offsite receptors than soil gas generated from impacted groundwater that has migrated offsite (as the "source" would be moving closer to the receptor).

– Considering the existing and future Site conditions and current lack of identified preferential pathways in the vadose zone, the primary migration mechanism for soil gas would be expected to be diffusion and as a result the potential for risks to offsite receptors via the lateral migration of soil gas from soil sources is considered low. Utility corridors can provide a preferential path for contaminated groundwater or volatile transport. Based on the depth of groundwater, the typical depth of underground utilities (1.5 mbgs or deeper), and the presence of permeable materials onsite to the shallow onsite bedrock, COCs are most likely to be transported (that is, to migrate) via groundwater. RMMs are proposed to mitigate risks to receptors in offsite buildings from offsite groundwater migration.

- No unacceptable risks from inhalation of volatiles in outdoor air are expected for offsite Surface Receptors but unacceptable risks are possible for offsite Construction and Utility Workers working in trenches if impacted groundwater migrates offsite.

4.4.3.3 Qualitative Assessment of Direct Contact Exposure – Vapour Skin Contact

Dermal exposure to vapours can be an important pathway in HHRAs—particularly for occupational settings where receptors are wearing a respirator because most of the body burden would likely be derived from dermal exposure. However, with few exceptions, dermal exposure to vapours is generally not considered in HHRAs, as supported by the following documents:

- EPA, 1989 — *Risk Assessment Guidance for Superfund* (RAGS): "Dermal absorption of vapour phase chemicals is considered to be lower than inhalation intakes in many instances and generally is not considered in Superfund exposure assessments."
- EPA, 1992 — *Dermal Exposure Assessment: Principles and Applications*: "Current studies suggest that dermal exposure may be expected to contribute no more than 10% to the total body burden of those compounds present in the vapour phase."
- McDougal and Boeniger, 2002 — "Methods for assessing risks of dermal exposures in the workplace": "In most cases, vapour absorption through the skin would not be of concern unless a respirator is worn because the majority of the body burden would come from inhalation."
- EPA, 2007 — *Dermal Exposure Assessment: A Summary of EPA Approaches*: "Dermal exposures to chemicals present in air are considered unlikely, in most cases, to provide more than 10% of aggregate exposure."

Numerous regulatory documents and scientific journals provide methodologies and equations that can be used to estimate the dermal absorption of chemical vapours (for example, EPA, 1992; McDougal and Boeniger, 2002). At least four different methods can be used to predict an internal dose once an external dose has been estimated. The methods differ in the type and quantity of information required for the calculations, in the simplifying assumptions that are made, and in the reliability of the results. Internal dose can be predicted from external dose based on the following:

- The empirical measurement of fraction of applied dose absorbed
- Measured (or estimated by correlations) steady-state flux or permeability
- Steady-state flux or permeability adjusted by the square root of time
- Biologically based mathematical models (McDougal and Boeniger, 2002)

The equations available for quantifying dermal absorption of chemical vapours are typically simplistic (and often inaccurate), as they do not account for many exposure factors, including the following:

- Individual variability of skin penetrability due to age of the individual and skin condition (for example, broken or damaged skin)
- Variances in the penetrability of the skin in different areas of the body
- Individual variability in the amount of skin available for exposure (that is, clothing or gloves worn)
- Temperature and humidity (both have been shown to affect dermal absorption of chemical vapours)
- Evaporation from skin following deposition onto skin

Estimates of internal dose often rely on information gained from animal studies. However, rodents (frequently used as a model for human exposure and risk) have a different, more permeable skin structure than humans; and, in most cases, there is more penetration data for rodents than for humans. This usually necessitates the use of physiologically based pharmacokinetic modelling, which can further increase the uncertainty of internal dose estimates. Therefore, while dermal exposure to vapours is a potentially complete pathway at the RA Property, Jacobs did not quantitatively evaluate this pathway, given the uncertainty associated with its quantification and the general belief that it does not contribute greatly to a receptor's overall exposure and body burden unless the receptor is wearing a respirator (which is not anticipated at the RA Property).

4.4.3.4 Qualitative Assessment of Contaminants of Concern with Concentrations Less than MECP Component Values

As outlined in Section 4.1.2, a secondary screening against MECP-derived human health component values (MECP, 2011b) was completed for the COCs to determine which would be evaluated quantitatively or qualitatively in the HHRA. Tables 4-1 and 4-2 present the results of this screening for soil and groundwater, respectively. Qualitatively assessed COCs include those with maximum concentrations greater than the Table 6 SCS, but estimated maximum concentrations less than the MECP-derived human health component values (direct contact pathways), or maximum theoretical indoor air concentrations less than HBIAC values and maximum concentrations less than the human health component values (for inhalation pathways). For these COCs, risks to receptors (including Pregnant Females) are considered to be less than the MECP target cancer and noncancer risk levels. Therefore, the proposed human health PSSs are based on the estimated maximum concentration of each COC.

4.4.3.5 Qualitative Assessment of Parameters without Toxicity Data

Lead

Lead was retained as a COC in soil and groundwater for quantitative evaluation in the HHRA, since the estimated maximum concentrations in both media were greater than the Table 6 SCS. Recent science suggests any exposure to lead may result in an adverse effect, especially to infants and children. The current Canada BLL "intervention level" is 10 µg/dL; however, there is evidence to suggest adverse impacts at lesser BLLs (as low as 1 to 2 µg/dL) (Health Canada, 2013). Therefore, there are uncertainties associated with TRVs that have not considered the potential adverse health effects associated with lower BLLs, including those used to derive the generic MECP standards.

The Rationale Document (MECP, 2011b) acknowledges that lead was an exception in the development of the generic standards and human health component values:

> *"For some substances, a threshold for non-cancer effects may not exist, or may not be possible to discern. In such instances, establishing a guideline or standard cannot be based on target HQ. Instead, the guideline or standard may be based on a policy decision regarding an acceptable level of adverse effect or uncertainty. Lead is an example of such a substance."*

In response to the changing science, various regulatory agencies, including EPA and Health Canada, are in the process of reassessing their previously published policies, TRVs, and soil and groundwater quality guidelines for lead. As a result, Jacobs did not quantify exposure and risk from oral and dermal contact with lead in soil or groundwater within the HHRA.

A qualitative evaluation of oral, dermal, and inhalation (dust) exposures to lead has been conducted using the MECP *Table 1 Full Depth Background Site Condition Standards* (Table 1 Standard) (MECP 2011c), which represent background conditions in Ontario. The background soil and groundwater values are considered appropriate to determine whether lead concentrations measured at the RA Property may pose a risk to human health greater than that expected at an Ontario property that has not been impacted by anthropogenic activities. The estimated maximum concentration of lead in soil at the RA Property is 12,000 µg/g, which is 100 times greater than the MECP Table 1 Standard for lead of 120 µg/g. Seventy-six soil samples (approximately 33 percent of soil samples analyzed for metals) had concentrations of lead exceeding 120 µg/g. Therefore, this elevated lead concentration in soil may pose a risk to onsite receptors at the RA Property and offsite Surface Receptors and Workers.

The estimated maximum concentration of lead in groundwater at the RA Property is 17 µg/L, which is 9 times greater than the MECP Table 1 Standard for lead of 1.9 µg/L. Four groundwater samples (approximately 2 percent of groundwater samples analyzed for metals) had concentrations of lead exceeding 1.9 µg/L. Therefore, this elevated lead concentration in groundwater may pose a risk to onsite receptors at the RA Property and offsite Surface Receptors and Workers.

To mitigate the potential risks from direct contact with lead in soil and groundwater, and inhalation of lead in soil, RMMs to prevent or reduce contact with lead-impacted soils and groundwater are recommended as part of the RMP (Section 7). As RMMs will be implemented, the proposed human health PSSs for lead are based on the estimated maximum concentration of lead currently remaining onsite.

Bismuth

A literature search was performed to identify one of more of: Ontario or Canadian background concentrations for bismuth, human health soil screening values, or agency-approved TRVs for bismuth. As a result of this search, only one human health specific soil screening value was identified. The Texas Commission on Environmental Quality (TCEQ), as part of their Texas Risk Reduction Program, has derived a Protective Concentration Level (PCL) (TCEQ 2021) for bismuth for residential receptors. The PCLs consider direct contact (ingestion and dermal) with soil and ingestion of vegetables grown in impacted soil. The PCL derived by TCEQ for bismuth is 37,000 µg/g for residents based on the direct contact pathways only. The value is based on non-carcinogenic risk using an RfD (oral) of 5.0E+01 mg/kg/day. The source of the TRV is listed as being derived directly by TCEQ; the supporting documentation for the derivation of this TRV was not readily available online. Due to the lack of information available for bismuth and the known low toxicity to humans via the intake of medicinal products (Wang et al.), the TCEQ value was determined to be adequate for use in the qualitative assessment. The TCEQ PCLs are based on a HQ of 1.0 (TCEQ 2008); therefore, the PCL was divided by 5 to adjust to a target HQ of 0.2 for use in this RA. Therefore, the adjusted soil screening level used for the qualitative assessment of bismuth is 7,400 µg/g.

The estimated maximum concentration of bismuth in soil at the RA Property is 180 µg/g, which is approximately 40 times lower than the adjusted soil screening value of 7,400 µg/g. Of the 103 soil samples analyzed for bismuth (12 samples as part of historical investigations and 91 samples as part of recent investigations), only 12 samples had detected concentrations, ranging from 1.7 µg/g to 150 µg/g. Therefore, the bismuth concentrations in soil are unlikely to pose a risk to onsite receptors at the RA Property and offsite Surface Receptors and Workers from oral, dermal, and inhalation (dust) exposures.

As RMMs will be implemented across the property for other COCs and no adverse impacts from bismuth are anticipated, the proposed human health PSS for bismuth is based on the estimated maximum concentration of bismuth currently remaining onsite.

Iron (Dust Only)

A qualitative evaluation of inhalation (dust) exposures to iron has been conducted using the MECP *Ontario Typical Range* (OTR) values (MECP 2011c), which represent background conditions in Ontario. The background soil values are considered appropriate to determine whether iron concentrations measured at the RA Property may pose a risk to human health greater than that expected at an Ontario property that has not been impacted by anthropogenic activities. The estimated maximum concentration of iron in soil at the RA Property is 150,000 µg/g, which approximately 4 times greater than the OTR for iron of 38,000 µg/g. Twenty-five of 135 soil samples (approximately 19 percent of soil samples analyzed for iron) had concentrations of iron exceeding 38,000 µg/g. Therefore, elevated iron concentrations in soil may pose a risk to onsite receptors at the RA Property and offsite Surface Receptors and Workers via the inhalation of dust. The known health effects from exposure to iron via inhalation associated with occupational exposures (such as welding activities) may include "irritation to eyes, skin, and respiratory tract" (from inhalation of aerosols or mists of soluble iron salts); "siderosis, a benign pneumoconiosis" and "accumulation of iron dust in the lungs" (from inhalation of ferric oxide dusts and fumes) (EPA, 2006).

To mitigate the potential risks from inhalation of iron in soil, RMMs to prevent or reduce dust generation are recommended as part of the RMP (Section 7). As RMMs will be implemented, the proposed human health PSS for iron is based on the estimated maximum concentration of iron currently remaining onsite.

Ecological Contaminants of Concern

One parameter that was not applicable to human health was retained as soil a COC via the screening process outlined in Section 3: EC. This parameter is included in the ERA presented in Section 5 of this RA. As human health toxicity data have not been developed for this parameter, Jacobs based the proposed human health PSS on the estimated maximum concentration.

Essential Nutrients

Essential nutrients are needed to maintain basic life functions. Because these chemicals are essential nutrients and they have relatively low toxicity to human health, TRVs may not have been developed for them. The physiologically essential levels for these nutrients are recommended for daily intakes from various health agencies worldwide. Values adopted by Health Canada (2010b) were used in the current assessment. Values used to determine the intake of essential nutrients at the Site include:

- Tolerable Upper Intake Level (UL) – The UL is the highest average daily nutrient intake level likely to pose no risk of adverse health effects to almost all individuals in a given life-stage and gender group.

- Adequate Intake (AI) – The AI is the average recommended daily allowance (RDA) of a nutrient based on observed or experimentally determined approximations or estimates of nutrient intake by a group (or groups) of apparently healthy people who are assumed to be maintaining an adequate nutritional state.

Using the UL and AI values described, the intake of essential nutrients detected at the RA Property (specifically, calcium and magnesium in soil) were calculated (Table 4-39) for a Toddler based on the soil ingestion rates used in the RA to determine if the intake from Site soil represents a significant proportion of the UL or AI values. The following subsections describe the results.

Calcium

Calcium occurs abundantly in nature as least soluble calcium compounds. Several foods are rich in calcium such as milk, cheese, green leafy vegetables, soybean products, fortified flour, and various nuts. The concentration of calcium in natural drinking water varies from less than 100 mg/L in soft water to 300 mg/L in hard water areas. Calcium intake is required for healthy bone formation, and the reference nutritional intake of calcium is 350 mg/day to 1,000 mg/day. Calcium is beneficial to health in reducing cell proliferation that is a precursor to certain forms of cancers and in reducing hypertension among adults. It is essential for skeletal structure and also is a cofactor in various enzyme metabolisms. TRVs were not developed for calcium as it is a nutritionally essential element and has relatively low toxicity (NIH 2021a)

- Calcium in Soil: The UL for calcium is 2,500 mg/day, and RDA/AI is 750 mg/day (based on a child 1-3 years old). Assuming a soil ingestion rate of 200 mg/day (based on the toddler soil ingestion exposure), with the estimated maximum concentration of calcium in soil of 260,000 mg/kg, receptor intake is estimated to be 52 mg/day, which is less than both the UL and the RDA/AI values. The proportion of the UL and RDA/AI, are approximately 2% and 7%, respectively. Therefore, detected concentrations of calcium in RA Property soil are unlikely to result in an adverse effect to human receptors at the Site.

Magnesium

Magnesium is the eighth most abundant element in the earth's crust and is ubiquitous in foods such as: leafy vegetables, grains, nuts, meats, and dairy. Magnesium is also used in antacids and as a food additive or supplement. It is essential for normal cell functioning as a cofactor for many enzyme systems and is required for "protein synthesis, muscle and nerve function, blood glucose control, and blood pressure regulation". Magnesium regulates the movement "of potassium and calcium ion across cell membranes". Magnesium is an important element in the metabolism and action of vitamin D and is essential for the synthesis and secretion of parathyroid hormone (NIH 2021b). Thus, TRVs have not been developed for magnesium.

- Magnesium in Soil: The UL for magnesium is 65 mg/day, and RDA/AI is 80 mg/day (based on a child 1-3 years old). The UL for magnesium does not account for food of water intake; therefore, the value appears to be biased low as it is less than the RDA/AI. Assuming a soil ingestion rate of 200 mg/day (based on toddler soil ingestion exposure), with the estimated maximum concentration of magnesium in soil of 140,000 mg/kg, receptor intake is estimated to be 28 mg/day, which is less than the UL and RDA/AI values. The proportion of the UL and RDA/AI, are approximately 35% and 43%, respectively. These proportions are higher than the analogous 20% of the TRV (HQ) used for evaluating noncancer risks. However, as magnesium is not volatile, daily exposures may be sourced from soil, water, food, and consumer products; therefore, assuming that a slightly higher proportion from soil would not result in an adverse effect may be appropriate. In addition, U.S. dietary surveys indicate that approximately 48% of people consume less than the RDA/AI of magnesium from food and beverages, with adolescents of both ages "most likely to have low intakes" (NIH 2021b). Considering this information, the detected concentrations of magnesium in RA Property soil are unlikely to result in an adverse effect to human receptors at the Site.

4.4.3.6 Qualitative Assessment of NAPL

The presence of NAPL has been confirmed at the RA Property in a limited area. Three monitoring wells (all screened within the overburden and bedrock contact zone aquifer unit) in the eastern portion of the Site have measured NAPL floating on the water table located right at or below the overburden and bedrock contact (refer to Figures 6-15, 6-15a, and 6-15b in Appendix D3). Therefore, additional consideration of potential risks related to NAPL, and the potential need for additional RMMs due to the presence of NAPL, is warranted. The MECP SCS and component values considered in the evaluation of COCs for the RA Property, and the equations applied in the calculations of risk and hazard, are based on the assumption that the petroleum hydrocarbons are distributed between the dissolved, vapour, and sorbed phases (that is, three phases are considered). With the limited area of NAPL present at the RA Property, nonaqueous-phase hydrocarbon could be present in addition to the dissolved, vapour, and sorbed phases (that is, four phases are present).

The presence of NAPL could have implications for the risk evaluations that rely on the application of partitioning equations (that is, movement to indoor air and outdoor air). Direct contact exposure to NAPL itself would also be possible in areas where NAPL is present. The quantitative assessment of risks due to impacts in soil and groundwater (Section 4.4.2) has already indicated unacceptable risks are present along the following pathways for PHCs:

- Human direct contact with soil (dermal and ingestion)
- Human direct contact with groundwater (dermal and ingestion)
- Inhalation of indoor air

The exposure pathways for which the estimated exposure and risk could be affected by the presence of NAPL include direct contact with soil and groundwater (dermal and ingestion) and inhalation (indoor and

outdoor). The inhalation of dust pathway is believed to be insignificant in the context of NAPL, as saturated soils would not become airborne. Each of these pathways is discussed below:

- Direct contact with Soil - As the MECP direct contact component values do not rely on partitioning equations (which may be invalidated by the presence of NAPL), the exposure and risk estimates previously presented (Section 4.4.2.1 and 4.4.2.4) for PHCs for this pathway are considered an estimate of the minimum risks that may occur in the presence of NAPL. RMMs (Section 7) were recommended for this pathway to reduce the risks to acceptable levels; the proposed RMMs will also be protective if NAPL is present.
- Direct contact with Groundwater – As the MECP direct contact component values do not rely on partitioning equations (which may be invalidated by the presence of NAPL), the exposure and risk estimates previously presented for Workers in contact with groundwater(Section 4.4.2.2 and 4.4.2.5) for PHCs for this pathway are considered an estimate of the minimum risks that may occur in the presence of NAPL. RMMs (Section 7) were recommended for this pathway to reduce the risks to acceptable levels; the proposed RMMs will also be protective if NAPL is present.
- Inhalation of Indoor Air – Risks to receptors in existing and future buildings were predicted from PHCs from both soil and groundwater sources. The exposure and risk estimates previously presented (Section 4.4.2.11) for PHCs for this pathway are considered an estimate of the minimum risks that may occur in the presence of NAPL. RMMs (Section 7) were recommended for this pathway to reduce the risks to acceptable levels; the proposed RMMs will also be protective where localized NAPL is present.
- Inhalation of Outdoor Air –The highest estimated outdoor air risk from PHC F2 was an HQ of 0.1 (for the Construction and Outdoor Worker, at the ground surface). This HQ is five times less than HQ for PHCs of 0.5. Considering the conservative assumptions that were assumed for the outdoor air modelling (for example, Jacobs selected the lowest average windspeed at the surface, ignored degradation and infiltration, and assumed receptors are exposed to the maximum soil or groundwater contraction for all exposures) and the limited extent of NAPL onsite, risks from outdoor air with respect to NAPL is considered low. Therefore, no RMMs are recommended for the outdoor air pathway for receptors at the surface even where NAPL is present. For Workers in a trench, the highest estimated outdoor air risk from PHC F2 for the Construction Worker was an HQ of 3.0, which greater than the acceptable HQ of 0.5 for PHCs. Therefore, it is possible that risks could be even greater for Workers in a trench in the presence of NAPL. RMMs (Section 7) were recommended for this pathway to reduce the risks to acceptable levels; the proposed RMMs will also be protective if NAPL is present.

In summary, the RMMs proposed in Section 7 for the protection of the direct contact with soil, groundwater, and vapour intrusion pathways are also adequate to protect receptors where NAPL is managed in place. Based on the qualitative evaluation of the localized presence of NAPL, additional RMMs are proposed to protect subsurface workers in contact with groundwater and working within trenches (outdoor air inhalation).

4.4.3.7 Qualitative Assessment of Ingestion Exposure - Home Garden Produce

As discussed in Section 4.2.2.1, there are significant uncertainties associated with quantifying exposure to home garden produce. As concentrations of COCs are present at levels greater than the Ontario background concentrations (that is, the Table 1 Standard [MECP, 2011c]), there is assumed risk from ingestion of produce grown on the RA Property. Therefore, RMMs will be proposed that prohibit the planting of fruit or vegetable gardens at the RA Property except in containerized plots or aboveground containers.

4.4.3.8 Qualitative Assessment of Inhalation of Soil Particulates that are Ingested

MassDEP (2008) provides guidance on assessing the ingested portion of soil (dust) particulates (greater than PM_{10} and less than PM_{30}). The fraction of inhaled particulate matter that is ultimately swallowed is assumed to be 1.4, which represents the fraction of all particles in air greater than PM_{10} and less than PM_{30} that are ingested (assumed to be 100% or a fraction of 1) plus the fraction of PM_{10} that is not deposited into the lungs (100% minus 60% [using the MECP assumption of 0.6] = 40% or a fraction of 0.4). Considering a sensitive receptor (pregnant female construction worker) and using other MECP defaults for the particulate concentration in air, body weight, inhalation rate, and exposure duration combined with an assumed contaminant concentration in soil of 1 µg/g, the particulate ingestion dose is approximately 3.E-09 mg/kg/day. Incidental ingestion exposure based on Site-specific COC concentrations in soil for this receptor are several orders-of-magnitude higher, ranging from 3.E-06 to 1.E-01 mg/kg/day. Adding the estimated exposure for the two ingestion pathways results in an insignificant change to the overall ingestion exposure. These results indicate that the particulate (dust) ingestion pathway does not contribute significantly to the overall risk for ingestion when default MECP assumptions are applied. This conclusion may differ under certain scenarios where PM_{10} concentrations could be generated at levels greater than the typical MECP default. For the current RA, the risk estimates based on the conventional incidental soil ingestion pathway are sufficient to base risk management decisions on. Since the contribution of soil ingestion to the overall exposure is considered negligible for this sensitive receptor/COC combination, it is assumed to be negligible for all other less sensitive receptor/COC combinations.

4.4.3.9 Qualitative Assessment of Soil Odour Pathway

The Rationale Document (MECP, 2011b) contains aesthetic criteria for soil odour (S-Nose component) which contemplates a receptor smelling soil while gardening. A qualitative assessment was completed to determine the potential for aesthetic effects associated with onsite soils. The following COC had an estimated maximum concentration in soil greater than the S-Nose component[6]:

- Methylnaphthalene 1,2- (9 samples with concentrations greater than the S-Nose component)

Based on this comparison to the S-Nose values, the potential for elevated soil odour cannot be ruled out; however, it is noted again that the S-Nose values were evolved to be protective of a scenario where a receptor may smell a handful of soil at close range while gardening. Given that RMMs (specifically, capping and administrative controls) have been determined to be required to prevent direct contact with existing Site soils based on the quantitative evaluation, and gardening of home produce has been prohibited in Site soils, the potential for soil odour to cause an adverse effect at the Site is limited. With the implementation of these RMMs, Site soils with concentrations exceeding the S-Nose component values are expected to be located beneath a cap. Additionally, to address the potential for odour issues in soil used for fill caps, an olfactory screening step has been included in the soil management process for the construction of fill caps (Sections 7.2.2 and 7.2.3.2).

4.4.3.10 Qualitative Assessment of Potable Groundwater Odour Pathway

The Rationale Document (MECP, 2011b) contains aesthetic criteria for potable groundwater odour (GW1-Odour component). A qualitative assessment was completed to determine the potential for aesthetic effects associated with the use of onsite groundwater as a potable water source. The following COCs have an estimated maximum concentration in groundwater greater than the GW1-Odour component (Appendix F, Table F1-6):

[6] In the absence of a soil component table for Table 6 (MECP, 2011b), the S-Nose components from the table entitled *Soil Components for Table 2 – Full Depth, Potable Water Scenario* (Coarse Textured Soil, Residential/Parkland Land Use) was used.

- Methylnaphthalene 1,2-
- Naphthalene
- Trichloroethylene

Based on this comparison to the GW1-Odour values, the potential for groundwater odour cannot be ruled out if groundwater at the Site is used as a potable resource. Given that RMMs (specifically, a restriction on the installation of potable and commercial wells) have been determined to be required to prevent potable water use of the existing Site groundwater based on the quantitative evaluation, the potential for groundwater odour to cause an adverse aesthetic effect at the Site is limited. As the groundwater odour pathway is considered minor in comparison to the health-based direct contact pathway (quantitatively assessed in Section 4.4.2), no specific RMMs have been proposed to address the potential for groundwater odour. Section 7.2.3.6 describes the proposed potable and commercial well restriction RMM for the Site based on the results of the quantitative assessment.

4.4.3.11 Qualitative Assessment of Soil Leaching to Potable Groundwater

The MECP (2011b) has published soil values that are protective of human receptors from COCs in soil leaching to groundwater with subsequent use as potable water (S-GW1). Table F1-7 in Appendix F1 presents the S-GW1 component values (Table 2 values were used in the absence of Table 6-specific values); note, the MECP did not develop S-GW1 values for metals and inorganics (except for mercury), as these analytes are not considered mobile or are not significantly mobile under normal soil conditions (for example, if soil pH is within the acceptable range).

Based on the comparison to the S-GW1, 14 soil COCs were identified with estimated maximum concentrations in soil greater than the S-GW1 component value within the RA Property:

- Acenaphthene
- Benzo(a)anthracene
- Benzo(a)pyrene
- Benzo(b)fluoranthene
- Benzo(k)fluoranthene
- Chrysene
- Dibenzo(a,h)anthracene
- Ethylbenzene
- Fluoranthene
- Naphthalene
- PHC F3
- Phenanthrene
- Pyrene
- Trichloroethylene

The S-GW1 values are calculated using GW1 values, combined with partitioning and transport models. As an intermediate step in the MECP's calculation of the S-GW1 soil values, concentrations of COCs in groundwater that have leached from soil are estimated. However, site-specific groundwater data are available to directly consider groundwater concentrations, as data from 94 monitoring well locations across the RA Property are included in the RA dataset (refer to Appendix D2). These measured groundwater concentrations provide a more direct and site-specific reflection of actual groundwater conditions, including potential leaching from soil. Of the 14 COCs with soil concentrations greater than the site-specific S-GW1, all but one parameter (dibenzo[a,h]anthracene) were retained for further assessment in groundwater based on their maximum observed groundwater concentrations exceeding the generic Table 6 SCS (refer to Table F1-2 in Appendix F1). The maximum measured concentration of dibenzo[a,h]anthracene in groundwater was half the Table 6 SCS value based on 189 samples from 55 monitoring wells; therefore, this analyte was not retained as a groundwater COC. Leaching of this analyte from soil does not appear to be of concern at the Site.

Contamination at the RA Property resulted from historical sources. The RA considers groundwater data from 2007 to 2020; therefore, the past and present potential for contaminant leaching to groundwater is reflected by the currently measured groundwater concentrations. Based on this information, potential risks to human receptors from RA Property potable groundwater use were evaluated primarily by comparing measured groundwater concentrations to the GW1 values. Table F1-4 in Appendix F1 presents the GW1 component values. As the quantitative assessment of the direct contact with potable groundwater pathway considers all the soil COCs[7] which had concentrations greater than the S-GW1, the risk to human health has been appropriately assessed. No specific RMMs have been proposed for this pathway. Section 7.2.3.6 describes the proposed potable and commercial well restriction RMM for the Site based on the results of the quantitative assessment.

4.4.4 Human Health Standards Based on Quantitative and Qualitative Interpretation of Health Risks

The quantitative and qualitative assessment of exposure pathways indicate health risks are possible to current and future receptors for the exposure scenarios discussed. The rationales for the development of the PSSs that are protective of human health are discussed in this section. Risk management is proposed where the assessment indicated a potential risk at the PSS.

4.4.4.1 Development of Property-specific Standards

Jacobs selected the estimated maximum concentration, defined as the maximum plus 20 percent (of detected values) or the maximum reported detection limit (RDL), for each COC to be representative of a reasonable upper-estimate of actual soil and groundwater concentrations remaining on the RA Property. COCs were selected based on the Table 6 SCS and the shallow bedrock conditions have been considered in setting the PSS for the Site. Proposed PSSs for soil and groundwater applicable to human health were selected as described in the following subsections.

4.4.4.2 Soil

PSSs for COCs identified in soil were based on the following:

- The estimated maximum if no unacceptable risks were predicted in the quantitative or qualitative assessment
- The estimated maximum if unacceptable risks were predicted in the quantitative or qualitative assessments, and exposure pathways with risk exceeding target levels are eliminated using RMMs

Table 4-40 presents the PSS values selected for soil to be protective of human health.

4.4.4.3 Groundwater

PSSs for COCs identified in groundwater were based on the following:

- The estimated maximum if no unacceptable risks were predicted in the quantitative or qualitative assessment
- The estimated maximum if unacceptable risks were predicted in the quantitative or qualitative assessment, and exposure pathways with risk exceeding target levels are eliminated using RMMs

Table 4-40 presents the PSS values selected for groundwater to be protective of human health.

[7] Apart from dibenzo(a,h)anthracene, which is not a COC in groundwater.

4.4.5 Special Considerations

The special conditions for environmentally sensitive areas, shallow soil properties, and water bodies cited under Sections 41 and 43.1 of O. Reg. 153/04 apply to the RA Property. Specifically, due to shallow bedrock conditions on a portion of the property, the RA Property is considered a shallow soil property under Section 43.1. This condition was considered in the initial screening of chemicals by using the Table 6 SCS to determine the COCs to be assessed for the RA Property (Section 3.3). As such, the proposed PSSs for human health have accounted for the conditions cited under Section 43.1 of O. Reg. 153/04. Section 41 (for environmentally sensitive areas) and Section 43.1 (specifically with respect to water bodies) do not apply to the RA Property.

4.4.6 Interpretation of Off-Site Health Risks

The proposed PSSs for soil COCs (presented in Table 4-40) are not anticipated to result in a concentration exceeding the applicable generic MECP standard (inferred to be the Table 6 SCS) at the nearest offsite property. Soil has the potential to migrate offsite via dust originating from soils at the RA Property; however, this mechanism is unlikely to result in a material change to offsite soil concentrations. In addition, elevated risks from dust inhalation were identified only for the Pregnant Female Workers (Construction or Utility) for B(a)P and for the Construction Worker for B(a)P, cobalt, and zinc during construction activities. Elevated risks from lead and iron in dust were identified for all receptors, based on the qualitative assessment. The RMMs required during construction activities to reduce the potential risk to acceptable levels onsite would prohibit transmission of PAH- and metals-containing dust offsite.

The proposed PSSs for groundwater COCs (presented in Table 4-40) could result in concentrations exceeding the applicable generic MECP standards (Table 6 SCS) at the nearest downgradient offsite property if groundwater containing COCs at PSS concentrations greater than the applicable SCS migrates offsite. Table 4-41 lists the groundwater COCs for the RA Property and assesses whether the proposed PSSs are likely to result in an offsite exceedance of the Table 6 SCS (inferred to apply to the nearest downgradient offsite properties), and whether the parameter is mobile[8]. If the potential for an offsite exceedance could not be ruled out, the nearest offsite human receptor was identified.

Groundwater flow direction was considered in this assessment. As discussed in Section 3.2, the predominant groundwater flow direction in the Overburden and Bedrock Contact Zone is from the northeast to the southwest, with localized flow from west to east on western portion of the Site and localized flow from east to west on the eastern portion of the Site. Groundwater in the Eramosa Formation (Potentiometric surface), appears to flow predominantly to the east.

As indicated in Table 4-41, the potential for an offsite exceedance of the applicable generic MECP standard for several parameters cannot be ruled out. As these parameters have a PSS greater than the Table 6 SCS and can potentially be mobile in groundwater, they have the potential to pose a risk to a downgradient offsite property. Groundwater monitoring is proposed on Site for these parameters (Section 7).

Offsite groundwater quality can be addressed onsite by monitoring groundwater movement, allowing natural attenuation, and notifying appropriate stakeholders in the event of offsite migration.

[8] The potential for contaminant of concern (COC) mobility in groundwater was assessed using professional judgement considering the Site history, distribution of COCs in soil and groundwater, as well as the individual COC's physical and chemical properties. Guidance from the New Jersey Department of Environmental Protection (NJDEP, 2008) related to the mobility of chemicals based on the organic carbon partition coefficient was also considered. In general, volatile organic compounds (VOCs), "light" polycyclic aromatic hydrocarbons (PAHs), and "light" petroleum hydrocarbons (PHCs) were considered potentially mobile, while "heavy" PAHs and "heavy" PHCs are unlikely to be mobile.

4.4.7 Discussion of Uncertainty

By its very nature, RA is an uncertain endeavour. Assumptions must be made regarding receptors that are potentially exposed. Often, exposure point concentrations must be estimated via modelling or other estimation methods. Without exception, toxicity indices are developed by credible government agencies and are purposefully calculated in a conservative fashion to monitor that benchmarks for estimating toxicity effects have a sufficient margin of safety to protect human health.

4.4.7.1 Hazard Analyses and Problem Formulation

Hazard analyses and problem formulation are conservative in nature and are developed so potential elevated risks are identified at the RA Property. This section qualitatively evaluates the extent to which chemicals at the RA Property may cause adverse health effects on receptors of concern.

COCs have been detected in soil and groundwater at the RA Property, indicating a potential risk exists. The screening process is conservative and could lead to the identification of COCs (and their inclusion in the RA) that do not actually indicate a potential risk at the RA Property. The inclusion of these COCs in the RA has little effect on the conclusions of the evaluation.

4.4.7.2 Exposure Assessment

Uncertainty exists in the exposure assessment of the RA. Onsite receptors were hypothesized, and activities assumed to result in exposures, as follows:

- EDs and EFs were assumed to occur on a regular and long-term basis, despite the reasonable potential that receptors may relocate residences; therefore, may change recreational places, may change employment or job descriptions, and are unlikely to contact chemicals on a routine basis. The conservative way receptors have been identified and activities evaluated indicates that uncertainties in the exposure assessment most likely allow for an overestimation of risk.
- The exposure assessment section also defines the concentrations to which potential receptors may be exposed. Within the RA Property boundaries, vapour concentrations have been estimated using conservative models that incorporate general fate and transport factors intended to conservatively overestimate vapour concentrations to which exposures might occur. This approach results in an overestimate of exposure and associated risk to certain receptors. These conservative assumptions likely overestimate exposures to the COCs and, correspondingly, overestimate risk. These assumptions impart uncertainty to the RA but are developed to confirm the RA conclusions are conservative and protective of human health. The net effect of these uncertainties is that risk to potential receptors has likely been overestimated.
- Estimated maximum concentrations of chemicals in soil and groundwater were used in the modelling. Concentrations of contaminants are not uniformly distributed across the RA Property. These concentrations appear in localized areas on the RA Property and represent the greatest concentration based on judgmental sampling. Receptors would not consistently be exposed to the maximum concentrations present at the Site over their lifetime; therefore, the predicted risks have likely been overestimated.
- The selected incidental ingestion rates for soil and groundwater may be different from the experimental basis used to develop them (for example, Construction and Utility Worker incidental ingestion of groundwater is based on exposure while swimming and not incidental contact while working). Changes in ingestion rate would increase or decrease the predicted exposures and risk.
- The conditions at a site may not match the conditions during the study upon which the dermal adherence factor is based. For example, studies have found finer particles adhere preferentially to the hands unless soils are greater than 10 percent moisture. Some studies have found soil particles

greater than 250 micrometres (μ) do not adhere readily to skin (EPA, 2004). Thus, the soil type, including moisture content, can affect the adherence of soil. In addition, the specific activity that occurs in the site-specific exposure scenario may not directly match the activities on which adherence factors were based. These factors can introduce uncertainties into the exposure assessment.

4.4.7.3 Toxicological Information

There is a limited amount of toxicological information on the effects associated with human exposures to low levels of chemicals in the environment. What human information is available is generally based on epidemiological studies of occupationally exposed workers. These studies are generally limited in scope and provide results that may not apply to chronic or continuous exposures to low levels of chemicals. Because human toxicological information is limited, RfDs and cancer potency estimates for many compounds are based on the results of dose-response assessment studies using animals.

The use of experimental animal data to estimate potential biological effects in humans introduces uncertainties into the evaluation of potential human health effects. These estimations require that several assumptions be made, including:

- The toxicological effect reported in animals is relevant and could occur in humans.
- The extrapolation from high-dose studies to low-dose environmental exposures adequately represents the shape of the dose-response curve in the low-dose exposure range.
- Short-term exposures used in animal studies can be extrapolated to chronic or long-term exposures in humans.
- The uptake of a compound from a test vehicle (including drinking water and food) in animals will be the same as the uptake of the chemical from environmental media (soil, sediment, airborne particulate matter) in humans.
- The pharmacokinetic processes that occur in the test animals also occur in humans.

There are clearly a number of uncertainties associated with extrapolating from experimental animal data to humans. To address these weaknesses, regulatory agencies, such as Health Canada and EPA, incorporate several conservative assumptions to try and account for the uncertainties associated with this process. The uncertainties are accounted for by using UFs that serve to reduce the RfD to far less than the level at which adverse health effects have been reported in the test species. UFs are generally applied by factors of 10 and are used to account for the following types of uncertainties:

- Variation within the population (protection of sensitive members of the population)
- Differences between humans and the test species
- Differences in using short- or medium-term studies to estimate the health effects associated with long-term or chronic exposures
- Limitations in the available toxicological information

The magnitude of the UFs applied by the various regulatory agencies indicates the level of confidence that should be placed in the reference value. UFs typically range between 100 and 10,000, although some can be less than 10. The latter values are found for a few chemicals where sound and substantial human toxicological information is available to enable setting a toxicological end-point solely on the basis of human epidemiological information.

The application of UFs is intended to address technical uncertainties in toxicological data, and to confirm, as much as possible, that limited exposures that exceed the RfC will not result in adverse human health effects.

Because RAs that use these regulatory limits incorporate the conservatism used in the development of the toxicological information, the results can generally be viewed as being extremely conservative.

4.4.7.4 Risk Characterization

The risk characterization phase of the RA integrates toxicity and exposure information to determine the potential for adverse health effects. In large part, the uncertainty resulting at this phase of the RA is a direct result of those uncertainties that have been discussed previously. As such, based on the foregoing evaluation, health risk is largely overestimated. However, it is important to note that benchmarks constituting substantial risk are arbitrarily selected and, as such, become value judgments as to their significance. In all instances, the risks deemed to be significant (that is, one in a million cancer risks for exposures from source related chemicals) are small relative to health risks associated with typical activities in a modern society (that is, approximately one in three cancer risks from all societal exposures). This does not diminish the importance of the excess risk noted in this report. The following summarizes uncertainties relating to the assessment at the RA Property (included in Section 4.4.2):

- Concentrations of contaminants are not uniformly distributed across the RA Property. The estimated maximum detected values for chemicals in soil and groundwater were used in the modelling. These concentrations appear in localized areas on the RA Property and represent the greatest concentration based on judgmental sampling. Receptors would not consistently be exposed to the maximum concentration present at a site over their lifetime; therefore, the predicted risks have likely been overestimated.
- The incidental ingestion rates may be different than the experimental basis used to develop them. Changes in ingestion rate would increase or decrease the predicted risk.
- The model does not account for the removal of contaminants (from soil) from the receptors' hands by brushing or washing off. This overestimates the risk from exposure.
- The amount of groundwater assumed to be incidentally ingested by Construction and Utility Workers during construction activities in this assessment is equivalent to the amount considered to be ingested during swimming activities (50 mL, as specified by EPA [1989]). The actual ingestion of groundwater is likely to be insignificant.
- Typical construction activities include dewatering excavations; therefore, it is unlikely that Construction and Utility Workers will be exposed to groundwater. Less exposure will result in lesser risk estimates.
- The comparators used to predict risk (that is, RfC and UR) are values considered to be protective of lifetime exposure to chemicals—24 hours per day, 7 days per week, 52 weeks per year, for 70 years—and include adjustments for sensitive individuals in the human population. Therefore, for a human receptor, risks are overestimated for short-term exposure to chemicals that may be present in air from dust, as no person will occupy the RA Property for any duration consistent with the duration used to develop the comparators. Adjustment of the comparator for shortened duration would likely result in a decreased risk for receptors.
- Risks from dust to offsite receptors would likely be less than experienced by RA Property users, since the concentration of COC-impacted fugitive dusts diminishes with dispersion and dilution in air rapidly with distance (EPA, 2002a).
- Vapour concentrations inside a generic commercial or generic residential building were modelled assuming the structure lies directly over the estimated maximum soil or groundwater concentration detected at the RA Property (only for volatile COCs). This assumption is conservative; therefore, the predicted risks from indoor air inhalation have likely been overestimated.

- While developing indoor air and outdoor air volatile concentrations, the degradation of organic compounds was ignored. If degradation was included, the chemical concentration would decrease, resulting in a decrease the estimated risks.
- Due to uncertainties associated with the available TRVs for lead, which may not consider the potential adverse health effects at BLLs less than the current Canadian BLL intervention level of 10 µg/dL, exposure and risk to lead via the direct contact and inhalation routes have not been quantitatively assessed in the RA. Lead has also been identified as a developmental toxicant but was not assessed quantitatively via the Pregnant Female receptor, as no TRV protective of developmental effects to a foetus is available.
- Due to a lack of appropriate TRVs, risks to bismuth have been qualitatively assessed using an adopted soil screening value. The lack of a quantitative assessment for this COC has little effect on the conclusions of the evaluation. Since an elevated risk has already been determined for onsite receptors from other COCs, the recommendation that RMMs should be implemented at the RA Property is not affected by this uncertainty.

4.4.8 Risk-based Concentrations for Fill Caps

The fundamental approach to preventing contact with contaminated soils is to construct a cap or soil barrier where RMMs are required. The cap or barrier must prevent human exposure to COCs and prevent mobilization of the contaminants. The purpose of the barrier is to prevent direct contact without relying on personal protective equipment (PPE) or clothing. Cap risk-based concentrations are developed for the anticipated future land use scenario as mixed residential and commercial.

Risk-based concentrations (RBCs) for fill caps were developed based on dermal contact and incidental ingestion exposure to soil by the Resident, Construction Worker, Utility Worker, Outdoor Worker, Indoor Worker, and Pregnant Female Worker, for a future mixed residential and commercial land use scenario.

Soil RBCs based on inhalation, dermal, and ingestion exposures were developed by applying a target ILCR of 1×10^{-6}, a target HQ of 0.2 for all COCs except PHC, and a target HQ for PHC fractions and TCE (inhalation pathways only) of 0.5. The soil RBCs apply for soil pH ranges of 5 to 9.

Tables 4-42a and 4-42b present the soil RBCs relevant to human health based on the direct contact pathway (dermal contact and ingestion) for the residential land use scenario for residents and subsurface workers, respectively. MECP generic soil direct contact component values (that is, S1) were adopted as the direct contact RBCs for any COC not retained for quantitative assessment in the HHRA.

Tables 4-43a and 4-43b present the soil RBCs relevant to human health based on the inhalation of indoor air pathway for residential and commercial building uses, respectively. MECP generic soil-to-indoor-air component values based on building type (that is, the S-IA) were adopted as the inhalation RBCs for volatile COCs not retained for quantitative assessment in the HHRA.

Table 4-44 shows the selection and basis of the overall soil RBCs protective of human health for a mixed residential, parkland, and commercial land use. If the calculated direct contact or inhalation RBC was less than the Table 6 SCS, the Table 6 SCS was selected as the overall soil RBC. VI RMMs are required for all future buildings at the RA Property (Section 7).

Fill cap target concentrations are presented in Section 6 of this document.

Additional human health RBCs were calculated to support the requirement to report the percentage reduction in COC concentrations associated with the proposed RMMs (Section 7).

Tables 4-45a and 4-45b present the dermal groundwater contact RBCs for potable water contact and Worker incidental contact in the subsurface, respectively.

Table 4-46a and 4-46b present the groundwater RBCs for the inhalation of indoor air pathway for the generic commercial and residential scenarios, respectively.

Table 4-47 presents the inhalation of trench air RBCs. Values are derived for the media (soil or groundwater) that was driving the risk for this pathway for each COC.

RBCs were developed based on the TRVs presented in Section 4.3. Uncertainties associated with variations in the TRVs could increase or decrease the RBC estimates. However, the conclusion that these RBCs are protective of Site receptors can be considered valid despite changes to the TRV, since the derivation of TRVs includes modifying factors and UFs that may span several orders of magnitude.
